In dyeing, then, it is not only necessary to procure a mordant, which has a sufficiently strong affinity for the colouring matter and the cloth, and a colouring matter which possesses the wished-for colour in perfection, we must procure a mordant and a colouring matter of such a nature, that when *combined together* they shall possess the wished-for colour in perfection. It is evident, too, that a great variety of colours may be produced with a single dye stuff, provided we can change the mordant sufficiently.

408 How applied.

10. Every thing which tends to weaken the affinity between the mordant and the cloth, or between the mordant and the colouring matter, and every thing which tends in any way to alter the nature of the mordant, must injure the permanency of the dye: because, whenever the mordant is destroyed, there is no longer any thing to cause the dye stuff to adhere; and when its nature is altered, the colour of the dye must alter at the same time. All the observations, then, which were made in the last chapter, concerning the nature of colouring matters, and the changes to which they are subject, apply equally to mordants. These substances, indeed, are scarcely liable themselves to any alteration. They are of a much more simple nature, in general, than dye stuffs; and therefore not nearly so liable to decomposition. But when the colouring matter itself is altered, it comes to the same thing. Its affinity for the mordant being now destroyed, there is nothing to retain it.

As the permanency of a dye depends upon the degree of affinity between the mordant and the colouring matter, it is clear that a dye may want permanency, even though it resist the oxy muriatic acid, and all the other saline tests proposed by chemists. These substances may happen to have very little action on the dye stuff, and therefore may not affect it; yet it may soon disappear, in consequence of its want of affinity for the mordant.

11. The colouring matter with which cloth is dyed, does not cover every portion of its surface; its particles attach themselves to the cloth at certain distances from each other: for cloth may be dyed different shades of the same colour, lighter or darker, merely by varying the quantity of colouring matter. With a small quantity, the shade is light; and it becomes deeper as the quantity increases. Now this would be impossible, if the dye stuff covered the whole of the cloth. Newton has demonstrated, that colours are rendered faint when the rays of light which occasion them are mixed with white rays. Consequently, from cloth dyed of a light shade, a considerable quantity of white rays passes off unchanged: but this could not be the case if the stuff were covered with coloured matter; because all the white rays would be decomposed as they pass through the coloured matter. Therefore, in light shades, the colouring matter does not cover the cloth; its particles adhere to it, at a certain distance from each other, and from every part of the cloth which is uncovered, the white rays pass off unchanged. Even when the shade of colour is as deep as possible, the colouring particles do not cover the whole of the cloth, but are at a certain distance from each other. This distance, undoubtedly, is diminished in proportion to the deepness of the shade: for the deeper the shade, the smaller is the number of white rays which escape undecompos[e]d; the more, therefore, of the surface is covered, and, consequently, the smaller is the distance at which each of them is placed. A shade may be even conceived so very deep, that not a particle of white light escapes the action of the colouring matter; in which case, the distance between the particles of colouring matter could not exceed double that distance at which a particle of matter is able to act upon light.

409 Dye-stuffs do not cover the whole surface of the cloth.

410 Compound colours.

That the particles of colouring matter, even when the shade is deep, are at some distance, is evident from this well-known fact, that cloth may be dyed two colours at the same time. All those colours, to which the dyers give the name of *compound*, are in fact two different colours applied to the cloth at once. Thus cloth gets a *green* colour, by being first dyed *blue* and then *yellow*. The rays of light that pass from green cloth thus dyed are blue and yellow; by the mixture of which it is well known that green is produced. In this case, it is clear, that each of the colouring matters performs the very same office as if it were alone; and that the new colour is not produced by the combination of the two colouring matters. That part of the white light, reflected from the cloth, which passes through the blue colouring matter, is decomposed, and the blue rays only transmitted; and that part of the white light which passes through the yellow colouring matter is also decomposed, and only the yellow rays transmitted. It is clear, therefore, that both of the colouring matters equally cover the naked fibres of the cloth; consequently the one must be placed in the intervals of the other: wherefore the particles of each of the colouring matters are at some distance. Now the same effect happens how deep soever the shade be; and it makes no difference which of the two dyes be first given. Nay, if one of the dyes have a strong affinity for the cloth, and the other only a weak affinity, the latter will soon disappear, and leave the cloth of the [illegible]our which the first dye gives it.

The difference, then, in the shade of colour, and also the compound colours which cloth may receive, depend entirely upon the distance between the particles of the colouring matters attached to the cloth, and the possibility

Blue. lity of partly filling up the intervals, either with the same colouring matter, or with a different one.

Thus we have taken a view of the theory of dyeing, as far, at least, as it is at present understood. It remains for us still to give an account of the particular manner by which each of the colours is imparted to cloth. This shall be the subject of the three following chapters. In the *first* we shall treat of the manner of dyeing the simple colours; in the *second*, of dyeing the compound colours; and in the *third*, of dyeing cloth partially several different colours at the same time, or of that branch of the art of dyeing which is known in this country by the name of *calico printing*.

CHAP. IV. OF DYEING SIMPLE COLOURS.

THE colours denominated by dyers *simple*, because they are the foundation of all their other processes, are four; namely, *1st*, blue;—*2d*, yellow;—*3d*, red:—*4th*, black. To these they usually add a fifth, under the name of *root*, or brown colour. These shall form the subject of the following sections.

SECT. I. *Of BLUE*.

THE only colouring matters employed in dyeing blue are *woad* and *indigo*: attempts, indeed, have been made to dye with prussiat of iron; but these attempts have hitherto failed.

1. The *isatis tinctoria*, or *woad*, is a plant commonly enough cultivated in this kingdom, and even found wild in some parts of England. It is of a yellowish colour. Some persons think that it was this plant with which the ancient Britons stained their bodies, to make them appear terrible to their enemies. When arrived at maturity, this plant is cut down, washed, dried hastily in the sun, ground in a mill, placed in heaps, and allowed to ferment for a fortnight; then well mixed together, formed into balls, which are piled upon each other, and exposed to the wind and sun. In this state they gradually become hot, and exhale a putrid ammoniacal smell. The fermentation is promoted, if necessary, by sprinkling the balls with water. When it has continued for a sufficient time, the woad is allowed to fall to a coarse powder. In this state it is sold to the dyers.

2. Indigo, is a blue coloured powder extracted from the *indigofera tinctoria*, and from several other species of the same genus of plants, which are cultivated for that purpose both in the East and West Indies.

When the *indigofera* has arrived at maturity, it is cut a few inches above ground, placed in strata in a large vessel, and covered with water. The plants soon acquire heat, ferment, and discharge abundance of carbonic acid gas. When the fermentation is far enough advanced, which is judged of by the paleness of the leaves, the liquid, now of a green colour, is decanted into large flat vessels, where it is constantly agitated till blue flocculæ begin to make their appearance. Lime water is now poured in, which causes the blue flocks to precipitate. The colourless liquid is decanted off, and the blue sediment poured into linen bags. When the water has drained from it sufficiently, it is formed into small lumps, and dried in the shade. In this state it is sold to the dyer under the name of *indigo*.

Dr Roxbourgh, who first drew the attention of manufacturers to the *nerium tinctorium*, a tree very common in Indostan, from the leaves of which indigo may be extracted with much advantage, has given a much shorter method of obtaining that pigment. The leaves are kept in a copper full of water, supported at the temperature of 160°, till they assume a yellowish hue, and the liquid acquire a deep green colour. The liquid is then to be drawn off, agitated in the usual manner, till the blue flocculæ appear; and then the indigo is be precipitated with lime water *.

This process, which succeeds equally well with the indigofera, shews us that the plants, from which indigo may be extracted, contain a peculiar green pollen, soluble in water. The intention, both of the fermentation of the common method, and of the scalding, according to Dr Roxbourgh's method, is merely to extract this pollen. Mr Haussman first shewed, that this green basis of indigo has a strong affinity for oxygen; and the subsequent experiments of Drs Roxbourgh and Bancroft have confirmed his observations, and put them beyond the reach of doubt. It gradually attracts oxygen from the air; in consequence of which, it acquires a blue colour, and becomes insoluble in water. The agitation is intended to facilitate this absorption, by exposing a greater surface to the action of the air. The lime water, by absorbing a quantity of carbonic acid, with which the green pollen seems to be combined, greatly facilitates the separation of the indigo.

The method of preparing indigo, and of applying it to the purposes of dyeing, seems to have been very early known in India. But in Europe, though it had been occasionally used as a paint *, its importance as a dye stuff was not understood before the middle of the 16th century. It is not even mentioned in the *Plictho*, which was published in 1548. At that period, then, the use of indigo must have been unknown to the Italian dyers. The Dutch were the people who first imported it from India, and made its importance known in Europe. It was afterwards cultivated in Mexico and the West Indies with such success, that the indigo from these countries was preferred to every other. In consequence of this preference, they supplied almost the whole of the European market. But within these few years, the East Indian indigo, owing entirely to the enlightened exertions of some of our own countrymen, has recovered its character, and is now imported, in very considerable quantities, into Britain.

The indigo of commerce has different shades of colour, according to the manner in which it has been prepared, and the proportion of foreign substances with which it is mixed. The principal shades are copper colour, violet, and blue. That indigo, which has the smallest specific gravity, is always most esteemed; because it is most free from impurities. Bergman † found the purest indigo of commerce which he could procure, composed of

47 pure indigo,
12 gum,
6 resin,
22 earth,
13 oxyd of iron.
100 (B).

(B) Proust informs us, that he found magnesia, even abundantly, in indigo.—*Nicholson's Jour.* III. 325.

Blue.

415 Its properties.

Pure indigo is insoluble in water, alcohol, ether, and oils: neither alkalies nor earths have any action on it; none of the acids hitherto tried have any effect on it, except the nitric and sulphuric. Nitric acid very soon converts it into a dirty white colour, and at last decomposes it completely*. When the acid is concentrated, it even sets fire to the indigo (c); when it is diluted, the indigo becomes brown, crystals make their appearance, resembling those of oxalic and tartarous acid, and there remains behind, after the acid and the crystals are washed off, a viscid substance, of a very bitter taste, and possessing many of the properties of a resin †.

* Berg. v.

† Hat.

Concentrated sulphuric acid dissolves indigo readily, and much heat is evolved. The saturated solution is opaque, and consequently black; but it assumes a deep blue colour when diluted with water. This solution is well known in commerce under the name of *liquid blue*. Bancroft has given it the name of *sulphat of indigo*. During the solution of the indigo, some sulphurous acid, and some hydrogen gas, are evolved ‡, and the blue colour of the indigo is much heightened. These facts have led Bancroft to suppose, that the indigo, during its solution combines with an additional quantity of oxygen *. This *may* possibly be the case, but the phenomena are not sufficient to establish it: for the hydrogen gas and sulphurous acid evolved may owe their formation not to the action of the sulphuric acid on indigo, but upon the impurities with which it is always mixed; and the improvement of the colour may be owing to the absence of these impurities. The carbonats of fixed alkalie precipitate slowly from sulphat of indigo a blue coloured powder, which possesses the properties of indigo; but it is soluble in most acids and in alkalies. Pure alkalies destroy the colour and properties of sulphat of indigo: they destroy also precipitated indigo §. These facts give some probability to Bancroft's opinion; but they do not establish it: because the differences between common and precipitated indigo may depend merely on the state of greater minuteness to which it is reduced, which prevents the attraction of aggregation from obstructing the action of other bodies. Even silica, when newly precipitated, is soluble in many menstrua.

§ Berg. v.

416 Method of dyeing with sulphat of indigo.

3. Indigo has a very strong affinity for wool, silk, cotton, and linen. Every kind of cloth, therefore, may be dyed with it, without the assistance of any mordant whatever. The colour thus induced is very permanent; because the indigo is already saturated with oxygen, and because it is not liable to be decomposed by those substances, to the action of which the cloth is exposed. But it can only be applied to cloth in a state of solution; and the only solvent known being sulphuric acid, it would seem at first sight that the sulphuric acid solution is the only state in which indigo can be employed as a dye.

The sulphat of indigo is indeed often used to dye wool and silk blue; but it can scarcely be applied to cotton and linen, because the affinity of these substances for indigo is not great enough to enable them readily to decompose the sulphat. The colour given by sulphat of indigo is exceedingly beautiful: it is known by the name of Saxon blue; because the process, which was discovered by councellor Barth in 1740, was first carried on at Grossenhayn in Saxony. The method of the original inventor was very complicated, from the great number of useless ingredients which were mixed with the sulphat. But these ingredients were gradually laid aside, and the composition simplified by others, after the nature of it, which was for some time kept secret, became known to the public. The best process is that of Mr Poerner *.

* Instruction sur l'Art de la Teinture, p. 183.

One part of indigo is to be dissolved in four parts of concentrated sulphuric acid; to the solution one part of dry carbonat of potass is to be added, and then it is to be diluted with eight times its weight of water. The cloth must be boiled for an hour in a solution, containing five parts of alum and three of tartar for every 32 parts of cloth. It is then to be thrown into a water bath, containing a greater or smaller proportion of the diluted sulphat of indigo, according to the shade which the cloth is intended to receive. In this bath it must be boiled till it has acquired the wished-for colour. The alum and tartar are not intended to act as mordants, but to facilitate the decomposition of the sulphat of indigo. Bergman ascertained that alum possesses this property. The alkali added to the sulphat answers the same purpose. These substances, also, by saturating part of the sulphuric acid, serve, in some measure, to prevent the texture of the cloth from being injured by the action of the acid, which is very apt to happen in this process.

417 Method of dyeing by decomposing indigo.

4. But sulphat of indigo is by no means the only solution of that pigment employed in dyeing. By far the most common method, and indeed the only method known before 1740, is to deprive indigo of the oxygen to which it owes its blue colour, and thus to reduce it to the state of green pollen; and then to dissolve it in water by means of alkalies, or alkaline earths, which in that state act upon it very readily. Indigo is precisely in the state of green pollen when it is first extracted from the plant in the scalding process described by Dr Roxbourgh. If, therefore, there were any method of stopping short here, and of separating the pigment while it retains its green colour, it would be precisely in the state best adapted for dyeing. Nothing more would be necessary but to dissolve it in water by means of an alkali, and to dip the cloth into the solution †.

† Bancroft.

But as indigo is not brought home to us in that state, the dyer is under the necessity of undoing the last part of the indigo maker's process, by separating again the oxygen, and restoring it to its original green colour. Two different methods are employed for this purpose. The first of these methods is to mix with indigo a solution of some substance which has a stronger affinity for oxygen than the green basis of indigo. Green oxyd of iron for instance, and different metallic sulphurets. If, therefore, indigo, lime, and green sulphat of iron, be mixed together in water, the indigo gradually

(c) The combustion of indigo by nitric acid, of the density 1.52°, was first published by Mr Sage; but Woulfe appears to have observed the fact before him, and to have pointed it out to Rouelle, who shewed it in his lectures. *Proust, Nicholson's Jour.* III. 325.

gradually loses its blue colour, becomes green, and is dissolved, while the green oxyd of iron is converted into the red oxyd. The manner in which these changes take place is obvious. Part of the lime decomposes the sulphat of iron; the green oxyd, the instant that it is set at liberty, attracts oxygen from the indigo, decomposes it, and reduces it to the state of green pollen. This green pollen is immediately dissolved by the action of the rest of the lime. In like manner, indigo is dissolved, when mixed in water, with pure antimony and potass, or with sulphuret of arsenic and potass. For these interesting facts we are indebted to Mr Hauffman.

The second method is to mix the indigo in water with certain vegetable substances which readily undergo fermentation. During this fermentation, the indigo is deprived of its oxygen, and dissolved by means of quicklime or alkali, which is added to the solution. The first of these methods is usually followed in dyeing cotton and linen; the second, in dyeing wool and silk.

418 How to induce a blue colour on wool,

5. In the dyeing of wool, woad and bran are commonly employed as vegetable ferments, and lime as the solvent of the green base of the indigo. Woad contains itself a colouring matter precisely similar to indigo; by following the common process, indigo may be extracted from it. In the usual state of woad, when purchased by the dyer, the indigo which it contains is probably not far from the state of green pollen. Its quantity in woad is but small, and it is mixed with a great proportion of other vegetable matter. Before the introduction of indigo into Europe, woad alone was employed as a blue dye; and even as late as the 17th century, the use of indigo was restricted in different countries, and dyers obliged to employ a certain quantity of woad (D). But these absurd restrictions were at last removed, and woad is now scarcely used in dyeing, except as a ferment to indigo. The blue colouring matter, however, which it contains, must, in all cases, contribute considerably to the dye.

A sufficient quantity of woad, mixed with bran, is put into a wooden vessel filled with warm water, whose temperature is kept up sufficiently to ensure fermentation. Afterwards quicklime and indigo are added. The indigo is deprived of its oxygen, and dissolved by the lime. When the solution is complete, the liquid has a green colour, except at the surface, where it is copper coloured, or blue, because the indigo at the surface absorbs oxygen from the air, and assumes its natural colour. The woollen cloth is dipped in, and passed thro' the liquid as equably as possible, piece after piece; those pieces being first dyed which are to assume the deepest shade. No part of the cloth should come in contact with the sediment, which would spoil the colour. When the cloth is first taken out of the vat, it is of a green colour; but it soon becomes blue, by attracting oxygen from the air. It ought to be carefully washed, to carry off the uncombined particles. This solution of indigo is liable to two inconveniences: 1. It is apt sometimes to run too fast into the putrid fermentation: this may be known by the putrid vapours which it exhales, and by the disappearing of the green colour. In this state it would soon destroy the indigo altogether. The inconvenience is remedied by adding more lime, which has the property of moderating the putrescent tendency. 2. Sometimes the fermentation goes on too languidly. This defect is remedied by adding more bran or woad, in order to diminish the proportion of quicklime. Yellow.

419 Silk,

6. Silk is usually dyed blue by the following process: Six parts of bran, and six of indigo, with nearly one part of madder, are stirred into a sufficient quantity of water, in which six parts of common potash of commerce is dissolved. The liquid is kept at a temperature proper for fermentation. When the indigo, deprived of its oxygen by the fermentation, is dissolved by the potash, the liquid assumes a green colour. The silk, previously well scoured, is put into the solution in small quantities at a time; then wrung out of the dye, and hung up in the open air, till the green colour which it has at first is changed into blue. By this method, silk can only be made to receive a light blue colour. In order to give silk a dark blue, it must previously receive what is called a ground colour: that is, be previously dyed some other colour. A particular kind of red dye-stuff, called *archil* (E), is commonly employed for this purpose.

The madder employed in the above process may, at first sight, appear superfluous: it seems, however, to contribute something to the colour.

Cotton and linen.

7. Cotton and linen are dyed blue by the following process: One part of indigo, one part of green sulphat of iron, and two parts of quicklime, are stirred into a sufficient quantity of water. The solution is at first green, but it gradually assumes a yellow colour, and its surface is covered with a shining copper coloured pellicle. The cloth is to be allowed to remain in the solution for five or six minutes. When taken out, it has a yellow colour; but on exposure to the atmosphere, it soon becomes green, and then blue, in consequence of the absorption of oxygen. The indigo, in this process, seems to be deprived of a greater quantity of oxygen than is necessary to reduce it to the state of green pollen. Mr Hauffman has observed, that the cloth acquires a much deeper colour, provided it be plunged, the instant it is taken out of the dyeing vat, into water acidulated with sulphuric acid. It is usual to dip the cloth into a succession of vats, variously charged with colouring matter; beginning with the vat which contains least colouring matter, and passing gradually to those which contain most. By this contrivance the cloth is dyed more equally, than it probably would be, if it were plunged all at once into a saturated solution of colouring matter.

SECT. II. *Of Yellow*.

421 Yellow dyes.

THE principal colouring matters employed to dye yellow are *weld*, *fustic*, and *quercitron bark*.

1. Reseda luteola, known in this country by the name of

(D) The employment of indigo was strictly prohibited in England in the reign of Queen Elizabeth; nor was the prohibition taken off till the reign of Charles II. It was prohibited also in Saxony. In the edict it is spoken of as a corrosive substance, and called *food for the devil*. Colbert restricted the French dyers to a certain quantity of it.

(E) This will be described in a subsequent section.

of weld, is a plant which grows wild very commonly in Scotland, and in most European countries. Cultivated weld is a more slender stalk than the wild kind, but it is more valuable, because it is much more rich in colouring matter. It is an annual plant, of a yellowish green colour, furnished with a great number of small leaves. When ripe it is pulled, dried, tied up in parcels, and in that state sold to the dyer.

Weld readily yields its colouring matter to water. The saturated decoction of it is brown; but when sufficiently diluted with water it becomes yellow. Acids render its colour somewhat paler, but alkalies give it a deeper shade. When alum is added to it, a yellow coloured precipitate falls down, consisting of alumina combined with the colouring matter of weld. The affinity therefore of this colouring matter for alumina is so great, that it is able to abstract it from sulphuric acid. Its affinity for oxyd of tin is at least equally great; for muriat of tin causes a copious bright yellow precipitate, composed of the colouring matter and the oxyd combined. Most of the metallic salts occasion similar precipitates, but varying in colour according to the metal employed. With iron, for instance, the precipitate is dark grey, and with copper brownish green *.

423 Fustic. 2. The *morus tinctoria* is a large tree which grows in the West India islands. The wood of this tree is of a yellow colour, with orange veins. The French call it *yellow wood (bois jaune)*; but the English dyers have given it the absurd name of *old fustic* (F). This wood has been introduced into dyeing since the discovery of America. The precise time is not known; but that it was used in England soon after the middle of the 17th century, is evident from Sir William Petty's paper on *Dyeing*, read to the Royal Society soon after its institution. In that paper particular mention is made of *old fustic*.

Fustic gives out its colouring matter with great facility to water. The saturated decoction of it is of a deep reddish yellow colour; when sufficiently diluted it becomes orange yellow. Acids render it turbid, give it a pale yellow colour, and occasion a slight greenish precipitate, which alkalies redissolve. Alkalies give the decoction a very deep colour, inclining to red; some time after they have been added, a yellow matter separates from the liquid, and either swims on the surface, or adheres to the sides of the vessel. Alum, sulphat of iron, of copper, and of zinc, produce precipitates composed of the colouring matter combined respectively with the bases of these different salts; and the colour varies according to the substance with which this colouring matter is combined. With alumina it is yellow; with iron, yellowish brown; with copper, brownish yellow; and with zinc, greenish brown †.

† Ib. ii. 269.

424 Quercitron. 3. The *quercus nigra*, to which Dr Bancroft has given the name of *quercitron*, is a large tree which grows naturally in North America. Dr Bancroft discovered, about the year 1784, that the bark of this tree contains a great quantity of yellow colouring matter, and since that time it has been introduced into dyeing with much advantage. To prepare it for the dyer, the epidermis is shaved off, and then it is ground in a mill. It separates partly into stringy filaments, and partly into a fine light powder. Both of these contain colouring matter, and therefore are to be employed; but as they contain unequal quantities, they should be used in their natural proportions.

Quercitron bark readily gives out its colouring matter to water at the temperature of 100°. The infusion has a yellowish brown colour, which is rendered lighter by acids, and darker by alkalies. Alum occasions a scanty precipitate of a deep yellow colour; muriat of tin, a copious bright yellow precipitate; sulphat of tin, a dark olive precipitate; and sulphat of copper, a precipitate of a yellow colour inclining to olive ‡.

‡ Bancroft, i. 320.

425 Other yellow dyes. 4. Besides these dye stuffs there are others occasionally used by dyers. The following are the most remarkable:

Genista tinctoria, or *dyers broom*. This plant yields a very inferior yellow; it is only used for coarse woollen stuffs.

Serratula tinctoria, or *saw-wort*. This plant yields a yellow nearly of the same nature with *weld*; for which, therefore, it is a good substitute.

Juglans alba, or *American hiccory*. The bark of this tree yields a colouring matter exactly similar to that of quercitron bark, but much smaller in quantity.

Anotta is a name given to a red paste formed of the berries of the bixa orellana, a tree which is a native of America. This paste yields its colouring matter to a solution of alkali in water. The solution affords an exceedingly beautiful yellow dye, but very fading, and incapable of being fixed by any known mordant.

Turmeric is the root of the *curcuma longa*, a plant which grows both in the East and West Indies. It is richer in colouring matter than any other yellow dye stuff. It yields very beautiful yellows, but too fading to be of much use, and no mordant has any influence in contributing to their permanence.

426 Yellow requires a mordant. 5. Yellow colouring matters have too weak an affinity for cloth to produce permanent colours without the use of mordants. Cloth, therefore, before it be dyed yellow, is always prepared by combining some mordant or other with it. The mordant most commonly employed for this purpose is alumina. Oxyd of tin is sometimes used when very fine yellows are wanted. Tan is often employed as a subsidiary to alumina, in order to fix it more copiously on cotton and linen. Tartar is also used as an auxiliary to brighten the colour; and muriat of soda, sulphat of lime, and even sulphat of iron, in order to render the shade deeper.

6. The yellow dyed by means of fustic is more permanent, but not so beautiful as that given by weld or quercitron. As it is permanent, and not much injured by acids, it is often used in dyeing compound colours where

(F) The *rhus cotinus*, or Venice sumach, is a small shrub, formerly employed as a yellow dye, but now almost out of use. The French call it *fustet*, from which word it is probable, as Dr Bancroft supposes, that our dyers formed the term *fustic*. When the *morus tinctoria* was introduced as a dye-stuff, they gave it the same name: but in order to distinguish the two, they called the sumach, which was a small shrub, *young fustic*; and the morus, which was a large tree, *old fustic*. See Bancroft i. 312.

Yellow. where a yellow is required. The mordant is alumina. When the mordant is oxyd of iron, fustic dyes a good permanent drab colour.

Weld and quercitron bark yield nearly the same kind of colour; but as the bark yields colouring matter in much greater abundance, it is much more convenient, and, upon the whole, cheaper than weld. It is probable, therefore, that it will gradually supersede the use of that plant. The method of using each of these dye stuffs is nearly the same.

427 Method of inducing a yellow colour on wool, 7. Wool may be dyed yellow by the following process: Let it be boiled for an hour, or more, with about $\frac{1}{6}$th of its weight of alum, dissolved in a sufficient quantity of water. It is then to be plunged, without being rinced, into a bath of warm water, containing in it as much quercitron bark as equals the weight of the alum employed as a mordant. The cloth is to be turned through the boiling liquid till it has acquired the intended colour. Then a quantity of clean powdered chalk, equal to the hundredth part of the weight of the cloth, is to be stirred in, and the operation of dyeing continued for eight or ten minutes longer. By this method a pretty deep and lively yellow may be given fully as permanent as weld yellow *.

For very bright *orange*, or *golden yellows*, it is necessary to have recourse to the oxyd of tin as a mordant. A fine orange yellow may be given to woollen cloth, by putting, for every ten parts of cloth, one part of bark into a sufficient quantity of hot water; after a few minutes, an equal weight of murio-sulphat of tin is to be added, and the mixture well stirred. The cloth acquires the wished for colour in a few minutes when briskly turned in this bath †.

The same process will serve for producing *bright golden yellows*, only some alum must be added along with the tin. For the brightest golden yellow, the proportions sufficient for dyeing 100 parts of cloth are, 10 parts of bark, 7 parts of murio-sulphat of tin, and 5 parts of alum. All the possible shades of golden yellow may be given to cloth merely by varying the proportion of the ingredients according to the shade ‡.

In order to give the yellow that delicate *green* shade so much admired for certain purposes, the same process may be followed, only tartar must be added in different proportions according to the shade. Thus to dye 100 parts of cloth a *full bright yellow*, delicately inclining to *green*, 8 parts of bark, 6 of murio-sulphat, 6 of alum, and 4 of tartar, are to be employed. The tartar is to be added at the same time with the other mordants. If the proportion of alum and tartar be increased, the green shade is more lively: to render it as lively as possible, all the four ingredients ought to be employed in equal proportions. As these fine lemon-yellows are generally required only pale, 10 parts of each of the ingredients will be sufficient to dye about 300 parts of cloth §.

By adding a small proportion of cochineal, the colour may be raised to a fine orange, or even an aurora ‖.

428 Silk, 8. Silk may be dyed different shades of yellow, either by weld or quercitron bark, but the last is the cheapest of the two. The proportion should be from 1 to 2 parts of bark to 12 parts of silk, according to the shade. The bark, tied up in a bag, should be put into the dyeing vessel while the water which it contains is cold, and when it has acquired the heat of about 100°, the silk, previously alumed, should be dipped in, and continued till it assumes the wished for colour. When the shade required is deep, a little chalk or pearlash should be added towards the end of the operation. When a very lively yellow is wanted, a little murio-sulphat of tin should be added, but not too much, because tin always injures the glossiness of silk. The proportions may be 4 parts of bark, 3 of alum, and 2 of murio sulphat of tin ¶.

Silk is dyed fine orange and aurora colours by annotta. The process is merely dipping the silk into an alkaline solution of annotta. To produce the orange shade the alkali is saturated with lemon juice. The colours thus produced are exceedingly beautiful, but they want permanency.

429 [Cotton and linen.] 9. The common method of dyeing cotton and linen yellow, has been described in the article DYEING in the *Encyclopædia*. The cloth is first soaked in a solution of alum, and then dyed in a decoction of weld. After this it is soaked for an hour in a solution of sulphat of copper, and, lastly, it is boiled for an hour in a solution of hard soap. This process, besides the expence of it, is defective; because the yellow is neither so beautiful nor so permanent as it might be if the mordant were used in a different form.

The method recommended by Dr Bancroft is much more advantageous, yielding more permanent and beautiful colours at a smaller expence. The mordant should be acetite of alumina, prepared by dissolving 1 part of acetite of lead, and 3 parts of alum, in a sufficient quantity of water. This solution should be heated to the temperature of 100°, the cloth should be soaked in it for two hours, then wrung out and dried. The soaking may be repeated, and the cloth again dried as before. It is then to be barely wetted with lime water, and afterwards dried. The soaking in the acetite of alumina may be again repeated; and if the shade of yellow is required to be very bright and durable, the alternate wetting with lime water, and soaking in the mordant, may be repeated three or four times. By this contrivance a sufficient quantity of alumina is combined with the cloth, and the combination is rendered more permanent by the addition of some lime. The dyeing bath is prepared by putting 12 or 18 parts of quercitron bark (according to the depth of the shade required), tied up in a bag, into a sufficient quantity of cold water. Into this bath the cloth is to be put, and turned round in it for an hour, while its temperature is gradually raised to about 120°. It is then to be brought to a boiling heat, and the cloth allowed to remain in it after that only a few minutes. If it be kept long at a boiling heat the yellow acquires a shade of brown *.

Another way of dyeing cotton and linen very permanent yellows, would be to imitate the method adopted for dyeing cotton in the East. That method is indeed exceedingly tedious, but it might be very much shortened by carefully attending to the uses of the ingredients. The essential part of the process is to cause the alumina to combine in sufficient quantity with the cloth, and to adhere with sufficient firmness to ensure a permanent colour. This is accomplished by using three mordants; first oil, then tan, and lastly alum. The combination of these three substances produces a mordant which ensures a very permanent colour.

The cotton is first soaked in a bath composed of a sufficient quantity of oil, and mixed with a weak solution

Yellow.

tion of soda. Animal oil seems to answer best for the purpose. Vogler found that glue answered extremely well. The soda should be caustic: In that state it combines with the oil and enables the cloth to absorb it equally. It is then, after being washed, put into an infusion of nut galls (the whiter the better). The tan combines with the oil, while the gallic acid carries off the alkali that may remain attached to the cloth. The infusion ought to be hot; and the cotton, after coming out of it, should be dried as quickly as possible. Care should be taken that the quantity of galls do not exceed a just proportion compared with the oil, otherwise the colour will be darkened. The cotton, thus prepared, is to be put into a solution of alum. There is a strong affinity between tan and alumina; in consequence of which, the alum is decomposed, and the alumina combines with the tan in sufficient abundance †. The cotton, thus prepared, is to be dyed, as above described, with quercitron bark.

† *Chaptal, Ann de Chim.* xxvi. 251.

430 Chaptal's process for cotton.

Mr Chaptal, whose ingenious labours have contributed exceedingly to elucidate the theory of dyeing, has proposed an exceedingly simple and cheap method of dyeing cotton a fine permanent nankeen yellow. His process is as follows (G).

Cotton has so strong an affinity for oxyd of iron, that if put into a solution of that oxyd in any acid whatever, it decomposes the salt, absorbs the iron, and acquires a yellow colour. The cotton to be dyed is to be put into a cold solution of sulphat of iron, of the sp. gr. 1.020; it is then wrung out, and put directly into a ley of potass, of the sp. gr. 1.010, into which a solution of alum has been poured till it was saturated with it. After the cotton has remained in this bath four or five hours, it may be taken out, washed, and dried. By this process cotton may be dyed all the different shades of nankeen, by varying the proportion of the sulphat of iron. This colour has the advantage of not being injured by washing, and of being exceedingly cheap §.

§ *Ibid.* 270.

SECT. III. *Of Red.*

431 Red dyes.

THE principal colouring matters employed in dyeing *red* are, *kermes*, *cochineal*, *archil*, *madder*, *carthamus*, and *Brazil wood*.

432 Kermes.

1. In different parts of Asia and the south of Europe, there grows a small species of oak, to which Linnæus gives the name of *quercus coccifera*. On this oak resides a small insect, of a reddish brown colour; in commerce it is known by the name of *kermes*. This insect is a species of *coccus*: Linnæus called it *coccus ilicis*. These insects are gathered in the month of June, when the female, which alone is useful, is swelled with eggs. They are steeped for ten or twelve hours in vinegar to kill the young insects contained in the eggs, and afterwards dried on a linen cloth. In this state they are sold to the dyer.

Kermes readily gives out its colouring matter to water or alcohol. It was much used by the ancients in dyeing; the colours which it produced were highly esteemed, being inferior in price only to their celebrated purple. They gave it the name of *coccus*.

Red.

The colour which it communicates to cloth is exceedingly permanent, but being far inferior in beauty to those which may be obtained from cochineal, it has been but little employed by dyers since that splendid pigment came into common use.

433 Cochineal.

2. Cochineal is likewise an insect, a species of *coccus*. Linnæus distinguishes it by the name *coccus cacti*. It inhabits different species of cacti, but the most perfect variety is confined to the *cactus coccinillifer*. The cochineal insect was first discovered in Mexico; the natives had employed it in their red dyes before the arrival of the Spaniards. It became known in Europe soon after the conquest of Mexico; and the beauty of the colour which it communicates to cloth very soon attracted general attention. For many years it was mistaken for a vegetable production, as had been the case also with the kermes. Different accounts of its real nature had indeed appeared very early in the Philosophical Transactions; but the opinion of Pomet, who insisted that it was the seed of a particular plant, gained so much credit, that it was not entirely destroyed till the publication of Mr Ellis's paper in the 52d volume of the Philosophical Transactions, which established the contrary beyond the possibility of doubt.

The female cochineal insect remains like the kermes, during her whole life adhering to a particular spot of the tree on which it feeds. After fecundation, her body serves merely as a nidus for her numerous eggs, and gradually swells as these advance towards maturity. In this state the insects are gathered, put into a linen bag, which is dipt into hot water to destroy the life of the young animals contained in the eggs, and then dried. In this state they are sent to Europe and sold to the dyer.

The quantity of cochineal disposed of in Europe is very great. Bancroft informs us, that the Spaniards annually bring to market about 600,000 lbs. of it. Hitherto the rearing of the insects has belonged almost exclusively to that nation. Other nations have indeed attempted to share it with them, but without any remarkable success; as the Spaniards use every precaution to confine the true cochineal, and even the species of cactus on which it feeds, to Mexico. Mr Thiery de Menonville was fortunate enough to procure some specimens of both, and to transfer them in safety to St Domingo; but after his death, the insects were allowed to perish. The wild cochineal insect, which differs from the cultivated kind merely in being smaller, and containing less colouring matter, was produced in St Domingo, in considerable quantities, before the commencement of the present war. Several spirited British gentlemen have lately contrived to procure the insect; and vigorous efforts are making to rear it in the East Indies. We have not yet learned the success of these attempts; but we have reason to hope every thing from the zeal and abilities of those gentlemen who have taken an active part in the enterprize.

Cochineal readily gives out its colouring matter to water. The decoction is of a crimson colour, inclining to violet: It may be kept for a long time without putrifying or losing its transparency. Sulphuric acid gives

(G) We ought to mention, that this process, or at least one very similar, has been long well known to the calicoe printers of this country. Most of their brown yellows, or drabs, are dyed with iron.

Red.

gives it a red colour, inclining to yellow, and occasions a small fine red precipitate. Tartar gives it a yellowish red colour, which becomes yellow after a small quantity of red powder has subsided. Alum brightens the colour of the decoction, and occasions a crimson precipitate. Muriat of tin gives a copious fine red precipitate; sulphat of iron, a brownish violet precipitate; sulphat of zinc, a deep violate precipitate; acetite of lead, and sulphat of copper, violet precipitates †.

Water is not capable of extracting the whole of the colouring matter of cochineal; but the addition of a little alkali or tartar enables the water to extract the whole of it *.

434 Archil.

3. Archil (H) is a paste formed of the *lichen roccella*, pounded and kept moist for some time with stale urine. It gives out its colouring matter to water, to alcohol (I), and to a solution of ammonia in water.

The lichen roccella grows abundantly in the Canary islands, from which it is imported and sold to the dyers. Other lichens are likewise used to dye red, especially the *parellus*, from which the pigment called *litmus*, and by chemists *tursole*, is prepared; the *omphalodes* and *tartareus*, which are often employed in this country to dye coarse cloths. To these many others might be added; but the reader may consult the treatises of Hoffman and Westring on the subject.

435 Madder.

4. The *rubia tinctorum* is a small well known plant, cultivated in different parts of Europe for the sake of its roots, which are known by the name of *madder*. They are about the thickness of a goose quill, somewhat transparent, of a reddish colour, and a strong smell. They are dried, cleaned, ground in a mill, and in that state used by dyers.

Madder gives out its colouring matter to water. The infusion is of a brownish orange colour; alum produces in it a deep brownish red precipitate; alkaline carbonats, a blood red precipitate, which is redissolved on adding more alkali. The precipitate occasioned by acetite of lead is brownish red; by nitrat of mercury, purplish brown; by sulphat of iron, a fine bright brown. After the red colouring matter has been extracted from madder by water, it is still capable of yielding a brown colour ‡.

436 Carthamus.

5. *Carthamus tinctorius* is an annual plant, cultivated in Spain, Egypt, and the Levant, for the sake of its flowers, which alone are used in dyeing. After the juice has been squeezed out of these flowers, they are washed repeatedly with salt water, pressed between the hands, and spread on mats to dry. Care is taken to cover them from the sun during the day, and to expose them to the evening dews, in order to prevent them from drying too fast. Such is the method followed in Egypt.

The flowers of carthamus contain two colouring matters; a yellow, which is soluble in water, and a red, insoluble in water, but soluble in alkaline carbonats. The method of preparing them above described, is intended to carry off the yellow colouring matter, which is of no use, and to leave only the red. After the flowers are thus prepared, they are of a red colour, and have lost nearly one-half of their weight. An alkaline ley readily extracts their colouring matter, which may be precipitated by saturating the alkali with an acid. Lemon juice is commonly used for this purpose, because it does not injure the colour of the dye. Next to citric, sulphuric acid is to be preferred, provided too great a quantity be not used. The red colouring matter of carthamus, extracted by carbonat of soda, and precipitated by lemon juice, constitutes the *rouge* employed by the ladies as a paint. It is afterwards ground with a certain quantity of talc. The fineness of the talc, and the proportion of it mixed with the carthamus, occasion the difference between the cheaper and dearer kinds of *rouge*.

437 Brazil wood.

6. *Brazil wood*, or *fernambouc*, as it is called by the French, is the wood of the *cæsalpinia crispa*, a tree which grows naturally in America and the West Indian islands. It is very hard; its specific gravity is greater than that of water; its taste is sweetish: its colour, when fresh cut, is pale; but after exposure to the atmosphere, it becomes reddish.

Brazil wood yields its colouring matter to alcohol, and likewise to boiling water. The decoction is of a fine red colour. The mineral acids make it yellow, and occasion a reddish brown precipitate. Oxalic acid causes an orange red precipitate. Fixed alkali gives the decoction a crimson colour, inclining to brown; ammonia, bright purple. Alum occasions a copious crimson precipitate, especially if alkali is added at the same time. Sulphat of iron renders the decoction black. The precipitate produced by muriat of tin is rose coloured; that by acetite of lead of a fine deep red *.

The decoction of Brazil wood is fitter for dyeing after it has stood some time, and undergone a kind of fermentation.

438 Red requires a mordant.

7. None of the red colouring matters has so strong an affinity for cloth as to produce a permanent red, without the assistance of mordants. The mordants employed are alumina and oxyd of tin; oil and tan, in certain processes, are also used; and tartar and muriat of soda are frequently called in as auxiliaries.

8. Coarse woollen stuffs are dyed red with madder or

† Berthollet, ii. 173.

* Ibid 175. and Bancroft, i. 271.

‡ Berthollet, ii. 115.

* Berthollet, ii. 240.

(H) If we believe Tournefort, this dye stuff was known to the ancients. They employed it to dye the colour known by the name of *purple* of Amorgos, one of the Cyclades islands. If this account be accurate, the knowledge of it had been lost during the dark ages. It was accidentally discovered by a Florentine merchant about the year 1300, who observed, that urine gave a very fine colour to the lichen roccella. Mr Dufay discovered, that archil possesses the property of tinging indelibly white marble, of forming veins, and giving it the appearance of jasper. See *Mem. Par.* 1732.

(I) The tincture of archil is used for making *spirit of wine thermometers*. It is a singular fact, that this tincture becomes gradually colourless when excluded from the contact of air, and that it again recovers its colour when exposed to the atmosphere. The phenomenon was first observed by the Abbé Nollet, and described by him in an essay, published among the memoirs of the Academy of Sciences for 1742.

Red. or archil; but fine cloth is almost exclusively dyed with cochineal; though the colour which it receives from kermes is much more durable. Brazil wood is scarcely used, except as an auxiliary; because the colour which it imparts to wool is not permanent.

439 Wool how dyed crimson, Wool is dyed *crimson*, by first impregnating it with alumina by means of an alum bath, and then boiling it in a decoction of cochineal till it has acquired the wished-for colour. The crimson will be finer if the tin mordant be substituted for alum: indeed it is usual with dyers to add a little nitro-muriat of tin when they want fine crimsons. The addition of archil and potass to the cochineal, both renders the crimson darker and gives it more bloom; but the bloom very soon vanishes. For paler crimsons, one half of the cochineal is withdrawn, and madder substituted in its place.

440 And scarlet Wool may be dyed *scarlet*, the most splendid of all colours, by first boiling it in a solution of murio-sulphat of tin; then dyeing it pale yellow with quercitron bark, and afterwards crimson with cochineal: For scarlet is a compound colour, consisting of *crimson* mixed with a little *yellow*. This method was suggested by Dr Bancroft, who first explained the nature of the common method. The proportions which he gives are eight parts of murio-sulphat of tin for 100 parts of cloth. After the cloth has been boiled in this solution for a quarter of an hour, it is to be taken out, and about four parts of cochineal, and two and a half parts of quercitron bark, are to be thrown into the bath. After these are well mixed, the cloth is to be returned again to the bath, and boiled in it, till it has acquired the proper colour *.

* Bancroft, i. 291.

The common process for dyeing scarlet is as follows: Twelve parts of tartar are dissolved in warm water; then one part of cochineal is added, and soon after ten parts of nitro-muriat of tin. When the bath boils, 100 parts of cloth are put in, turned briskly through the bath, boiled in it for two hours; then taken out, aired, washed, and dried. Into another bath eleven parts of cochineal are put; and after its colouring matter is sufficiently extracted, 28 parts of nitro-muriat of tin are added. In this bath the cloth is boiled for an hour, and then washed and dried.

Every preceding writer on dyeing took it for granted, that the yellow tinge necessary for scarlet was produced by the nitro-muriat of tin, or rather by the nitric acid of that compound, and that the tartar was only useful in enlivening the colour. But Dr Bancroft ascertained, by actual experiment, that nitro-muriat of tin has no such effect; that cloth, impregnated with this or any other tin mordant, and afterwards dyed with cochineal, acquires only a crimson colour, unless tartar be added; that the tartar has the property of converting part of the cochineal to yellow; and therefore is the real agent in producing the scarlet colour. Good scarlet, indeed, cannot be made without tin; because every other mordant sullies the colour, and renders it dull †.

† Ibid. 288.

441 Red dyes employed for silk, 9. Silk is usually dyed red with cochineal or carthamus, and sometimes with Brazil wood. Kermes does not answer for silk; madder is scarcely ever used for that purpose, because it does not yield a bright enough colour. Archil is employed to give silk a bloom; but it is scarcely used by itself, unless when the colour wanted is lilac.

Silk may be dyed crimson by steeping it in a solution of alum, and then dyeing it in the usual way in a cochineal bath. But the common process is to plunge the silk, after it has been alumed, into a bath formed of the following ingredients: Two parts of white galls, three parts of cochineal, three-sixteenths of tartar, and three-sixteenths of nitro-muriat of tin, for every sixteen parts of silk. The ingredients are to be put into boiling water in the order they have been enumerated; the bath is then to be filled up with cold water; the silk put into it, and boiled for two hours. After the bath has cooled, the silk is usually allowed to remain in it for three hours longer. 442 In dyeing crimson,

The colours known by the names of poppy, cherry, rose, and flesh colour, are given to silk by means of carthamus. The process consists merely in keeping the silk, as long as it extracts any colour, in an alkaline solution of carthamus, into which as much lemon juice as gives it a fine cherry colour has been poured. To produce a deep poppy red, the silk must be put successively into a number of similar baths, and allowed to drain them. When the silk is dyed, the colour is brightened by plunging it into hot water acidulated with lemon juice. The silk ought to be previously dyed yellow with anotta. 443 Poppy,

Cherry red is produced the same way, only the anotta ground is omitted, and less colouring matter is necessary. When a flesh colour is required, a little soap should be put into the bath, which softens the colour, and prevents it from taking too quickly. 444 Cherry, 445 Flesh red,

To lessen the expence, some archil is often mixed with carthamus for dark shades.

The same shades may be dyed by means of brazil wood, but they do not stand.

Silk cannot be dyed a full scarlet; but a colour approaching to scarlet may be given it, by first impregnating the stuff with murio-sulphat of tin, and afterwards dyeing it in a bath composed of four parts of cochineal and four parts of quercitron bark. To give the colour more body, both the mordant and the dye may be repeated *. A colour approaching scarlet may be also given to silk, by first dyeing it crimson, then dyeng it with *carthamus*, and lastly yellow without heat. †. 446 Scarlet.

* Bancroft, i. 312.

† Berthollet, ii. 203.

10. Cotton and linen are dyed red with madder. The process was borrowed from the East; hence the colour is often called *Adrianople* or *Turkey red*. The cloth is first impregnated with oil, then with galls, and lastly with alum, in the manner described in the last section. It is then boiled for an hour in a decoction of madder, which is commonly mixed with a quantity of blood. After the cloth is dyed, it is plunged into a soda ley, in order to brighten the colour. The red given by this process is very permanent, and when properly conducted it is exceedingly beautiful The whole difficulty consists in the application of the mordant, which is by far the most complicated employed in the whole art of dyeing. 447 How to dye cotton and linen red.

Cotton may be dyed scarlet by means of murio-sulphat of tin, cochineal, and quercitron bark, used as for silk; but the colour is too fading to be of any value *.

* Bancroft, i. 316.

SECT. IV. *Of Black.*

1. The substances employed to give a black colour to cloth are red oxyd of iron and tan. These two sub- 448 Black dyes.
stances

Black. stances have a strong affinity for each other; and when combined, assume a deep black colour, not liable to be destroyed by the action of air and light. The affinity which each of them has for the different kinds of cloth has been already mentioned.

2. Logwood is usually employed as an auxiliary, because it communicates lustre, and adds considerably to the fulness of the black. It is the wood of the tree called by Linnæus *hæmatoxylum campechianum*, which is a native of several of the West India islands, and of that part of Mexico which surrounds the Bay of Honduras. It yields its colouring matter to water. The decoction is at first a fine red bordering on violet, but if left to itself it gradually assumes a black colour. Acids give it a deep red colour; alkalies a deep violet, inclining to brown. Sulphat of iron renders it as black as ink, and occasions a precipitate of the same colour. The precipitate produced by alum is dark red; the supernatent liquid becomes yellowish red *.

* Berthollet, ii. 255.

3. Cloth, before it receive a black colour, is usually dyed blue. This renders the colour much fuller and finer than it otherwise would be. If the cloth be coarse, the blue dye may be too expensive; in that case a brown colour is given by means of walnut peels.

449 How to induce a black on wool,

4. Wool is dyed black by the following process. It is boiled for two hours in a decoction of nut galls, and afterwards kept for two hours more in a bath composed of logwood and sulphat of iron, kept during the whole time at a scalding heat, but not boiled. During the operation it must be frequently exposed to the air; because the green oxyd of iron, of which the sulphat is composed, must be converted into red oxyd by absorbing oxygen, before the cloth can acquire a proper colour. The common proportions are five parts of galls, five of sulphat of iron, and 30 of logwood for every 100 of cloth. A little acetite of copper is commonly added to the sulphat of iron, because it is thought to improve the colour.

450 Silk,

5. Silk is dyed nearly in the same manner. It is capable of combining with a very great deal of tan; the quantity given is varied at the pleasure of the artist, by allowing the silk to remain a longer or shorter time in the decoction. After the galling, the silk is put into a solution of sulphat of iron, which is usually mixed with a certain quantity of iron filings and of gum. It is occasionally wrung out of the bath, exposed for some time to the air, and again immersed. When it has acquired a sufficiently full colour, it is washed in cold water, and afterwards steeped in a decoction of soap to take off the harshness, which silk always has after being dyed black.

451 Linen, and cotton.

6. It is by no means so easy to give a full black to linen and cotton. The cloth, previously dyed blue, is steeped for 24 hours in a decoction of nut galls. A bath is prepared, containing acetite of iron, formed by saturating acetous acid with brown oxyd of iron. Into this bath the cloth is put in small quantities at a time, wrought with the hand for a quarter of an hour, then wrung out and aired, again wrought in a fresh quantity of the bath, and afterwards aired. These alternate processes are repeated till the colour wanted is given. A decoction of alder bark is usually mixed with the liquor containing the nut galls.

It would probably contribute to the goodness and permanence of the colour, if the cloth, before being galled, were impregnated with oil, by being steeped in a mixture of alkaline ley and oil combined, as practised for dyeing cotton red.

own.

Sect. V. *Of Brown.*

That particular *brown* colour, with a cast of yellow, which the French call *fauve*, and to which the English writers on *dying* have appropriated the word *fawn*, though in fact a compound, is commonly ranked among simple colours; because it is applied to cloth by a single process. The substances employed to produce this colour are numerous; but we shall satisfy ourselves with enumerating the following:

Walnut peels are the green covering of the walnut. When first separated, they are white internally, but soon assume a brown, or even a black colour, on exposure to the air. They readily yield their colouring matter to water. They are usually kept in large casks, covered with water, for above a year, before they are used. To dye wool brown with them, nothing more is necessary than to steep the cloth in a decoction of them till it has acquired the wished-for colour. The depth of the shade is proportional to the strength of the decoction. The root, as well as the peel of the walnut tree, contains the same colouring matter, but in smaller quantity. The bark of the birch, also, and many other trees, may be used for the same purpose.

It is very probable, that the brown colouring matter is in these vegetable substances combined with tan. This is certainly the case in sumach, which is often employed to produce a brown. This combination explains the reason why no mordant is necessary; the tan has a strong affinity for the cloth, and the colouring matter for the tan. The dye stuff and the mordant are already, in fact, combined together.

Chap. V. Of Compound Colours.

Compound colours are produced by mixing together two simple ones; or, which is the same thing, by dyeing cloth first one simple colour, and then another. The result is a compound colour, varying in shade according to the proportions of each of the simple colours employed.

Compound colours are exceedingly numerous, varying almost to infinity, according to the proportions of the ingredients employed. They may be all arranged under the four following classes: 453 Division of compound colour.

Mixtures of 1. blue and yellow,
2. blue and red,
3. yellow and red,
4. black and other colours.

To describe all the different shades which belong to each of these classes, would be impossible; and even if it were possible, it would be unnecessary; because all the processes depend upon the principles laid down in the preceding chapters, and may easily be conceived and varied by those who understand these principles. In the following sections, therefore, it will be sufficient to mention the principal compound colours produced by the mixture of simple colours, and to exhibit a specimen or two of the mode of producing them.

Sect. I. *Of Mixtures of Blue and Yellow.*

The colour produced by mixtures of blue and yellow is

is green; which is distinguished by dyers by a great variety of names, according to the depth of the shade, or the prevalence of either of the component parts Thus we have *sea green, meadow* or *grass green, pea green*, &c. &c.

454 How induced 455 On wool Wool is usually dyed green by giving it first a blue colour, and afterwards dyeing it yellow; because, when the yellow is first given, several inconveniences follow: the yellow partly separates again in the blue vat, and communicates a green colour to it; and thus renders it useless for every other purpose, except dyeing green. Any of the processes for dyeing blue, described in the last chapter, may be followed; care being taken always to proportion the depth of the blue to the shade of green which is required. The cloth thus dyed blue may receive a yellow colour, by following the processes described in the last chapter for that purpose. When the sulphat of indigo is employed, it is usual to mix all the ingredients together, and to dye the cloth at once: the colour produced is known by the name of *Saxon*, or *English green*. One of the most convenient methods of conducting this process is the following:

Six or eight parts of quercitron bark, tied up in a bag, are to be put into the dyeing vessel, which should contain only a small quantity of warm water. When the water boils, six parts of murio sulphat of tin, and four parts of alum, are to be added. In a few minutes, the dyeing vessel should be filled up with cold water, till the temperature is reduced to about 130°. After this, as much sulphat of indigo is to be poured in as is sufficient to produce the intended shade of green. When the whole has been sufficiently stirred, a hundred parts of cloth are to be put in, and turned briskly for about fifteen minutes, till it has acquired the wished for shade *. By this method, a much more beautiful colour is obtained than is given by the usual process, in which fustic is employed to give the yellow shade.

456 Silk, Silk, intended to receive a green colour, is usually dyed yellow first, by means of weld, according to the process described in the last chapter; afterwards, it is dipped into the blue vat, and dyed in the usual manner. To deepen the shade, or to vary the tint, decoctions of logwood, anotta, fustic, &c. are added to the yellow bath. Or silk may be dyed at once green, by adding suitable proportions of sulphat of indigo to the common quercitron bark bath, composed of four parts of bark, three parts of alum, and two parts of murio sulphat of tin †.

457 Cotton, and linen. Cotton and linen must be first dyed blue, and then yellow, according to the methods described in the last chapter. It is needless to add, that the depth of each of these colours must be proportioned to the shade of green colour which it is the intention of the dyer to give.

* Bancroft, i. 336.

† Ibid. 346

SECT. II. *Of Mixtures of* BLUE *and* RED.

458 Violet, purple, lilac, THE mixture of blue and red produces *violet, purple*, and *lilac*, of various shades, and known by various names, according to the proportion of the ingredients employed. When the colour is deep, and inclines most to blue, it is called *violet*; but when the red is prevalent, it gets the name of *purple*. When the shade is light, the colour is usually called *lilac*. For violet, therefore, the cloth must receive a deeper blue; for purple, a deeper red; and for lilac, both of these colours must be light.

Wool is usually dyed first *blue*; the shade, even for violet, ought not to be deeper than that called *sky blue*; afterwards it is dyed scarlet, in the usual manner. The violets and purples are dyed first; and when the vat is somewhat exhausted, the cloth is dipped in which is to receive the lilac, and the other lighter shades. By means of sulphat of indigo, the whole process may be performed at once. The cloth is first alumed, and then dyed in a vessel, containing cochineal, tartar, and sulphat of indigo, in proportions suited to the depth of the colour required *. A violet colour may also be given to wool, by impregnating it with a mordant composed of tin dissolved in a mixture of sulphuric and muriatic acids, formed by dissolving muriat of soda in sulphuric acid: to which solution a quantity of tartar and sulphat of copper is added. The wool is then boiled in a decoction of logwood till it has acquired the wished for colour †.

Mixture of Blue and Red.

459 How induced on wool,

Silk is first dyed crimson, by means of cochineal, in the usual way, excepting only that no tartar, nor solution of tin, is employed: It is then dipped into the indigo vat till it has acquired the wished-for shade The cloth is often afterwards passed through an archil bath, which greatly improves the beauty of the colour. Archil is often employed as a substitute for cochineal: The silk first receives a red colour, in the usual way, by being dyed in an archil bath; afterwards it receives the proper shade of blue. The violet, or purple, given by this process is very beautiful, but not very lasting ‡. 460 Silk,

Silk may be dyed violet or purple at once, by first treating it with a mordant, composed of equal parts of nitro-muriat of tin and alum, and then dipping it into a cochineal bath, into which a proper quantity of sulphat of indigo has been poured. But this dye is fading; the blue colour soon decays, and the silk becomes red *.

Cotton and linen are first dyed blue, then galled, then soaked in a decoction of logwood; some alum and acetite of copper are added to the decoction, and the cloth is soaked again This process is repeated till the proper colour is obtained †. The colour produced by this method is not nearly equal in permanency to that described in this *Supplement* under the word IRON; to which we beg leave to refer the reader. The process there described has been long known; but Mr Chaptal has simplified it somewhat. 461 Cotton, and linen

† Berthollet ii. 337.

SECT. III. *Of Mixtures of* YELLOW *and* RED.

THE colour produced by the mixture of *red* and *yellow* is *orange*; but almost an infinity of shades results from the different proportions of the ingredients, and from the peculiar nature of the yellow employed. Sometimes *blue* is combined with red and yellow on cloth: the resulting colour is called *olive*. 462 Orange and olive

Wool may be dyed orange by precisely the same process which is used for scarlet, only the proportion of red must be diminished, and that of yellow increased. When wool is first dyed red with madder, and then yellow with weld, the resulting colour is called *cinnamon colour*. The mordant, in this case, is a mixture of alum and tartar. The shade may be varied exceedingly, by using other yellow dye stuffs instead of weld, and by varying the proportions, according to circumstances. Thus a reddish yellow may be given to cloth, by first dyeing it yellow, and then passing it through a madder bath. 463 How induced on wool,

Silk is dyed orange by means of carthamus: the method 464 Silk,

Mixtures of black with other Colours.

method has been deſcribed in the laſt chapter. Cinnamon colour is given to it by dyeing it, previouſly alumed, in a bath compoſed of the decoctions of logwood, Brazil wood, and fuſtic, mixed together.

Cotton and linen receive a cinnamon colour by means of weld and madder. The proceſs is complicated. The cloth is firſt dyed with weld and acetite of copper, then dipped in a ſolution of ſulphat of iron, then galled, then alumed, and then dyed in the uſual way with madder *.

For *olive*, the cloth is firſt dyed blue, then yellow, and laſtly paſſed through a madder bath. The ſhade depends upon the proportion of each of theſe colours. For very deep ſhades the cloth is alſo dipped into a ſolution of ſulphat of iron. Cotton and linen may be dyed *olive* by dipping them into a bath, compoſed of the decoction of four parts of weld and one of potaſs, mixed with the decoction of Brazil wood and a little acetite of copper †.

† *D'Apligny, ibid.* 345.

SECT. IV. *Of Mixtures of* BLACK *with other Colours.*

466
Greys, drabs, and browns.

STRICTLY ſpeaking, the mixtures belonging to this ſection are not mixtures of *black colours* with other colours, but combinations of the *black dye* with other colours; the ingredients of which, galls and brown oxyd of iron, being both mordants, variouſly modify other colouring matters by combining with them. Thus if cloth be previouſly combined with brown oxyd of iron, and afterwards dyed yellow with quercitron bark, the reſult will be a *drab* of different ſhades, according to the proportion of mordant employed. When the proportion is ſmall, the colour inclines to olive or yellow; on the contrary, the drab may be deepened or ſaddened, as the dyers ſpeak, by mixing a little ſumach with the bark *. The precautions formerly mentioned in applying the oxyd muſt be obſerved.

* *Bancroft*, i. 343.

It is very common to dip cloth already dyed ſome particular colour into a ſolution of ſulphat of iron, and galls or ſome other ſubſtance containing tan, called the *black bath*, in order to alter the ſhade, and to give the colour greater permanency. We ſhall give a few inſtances: greater minuteneſs would be inconſiſtent with the nature of this article.

Cloth dyed blue, by being dipped into the *black* bath, becomes *bluiſh grey*. Cloth dyed *yellow*, by the ſame proceſs, becomes *blackiſh grey*, *drab*, or *yellowiſh brown*. Cloth previouſly alumed, and dyed in a decoction of cochineal and acetite of iron, acquires a permanent *violet colour* inclining to *brown*, or a *lilac*, if the dyeing veſſel be ſomewhat exhauſted *. Cloth ſteeped in a mordant, compoſed of alum and acetite of iron diſſolved in water, and afterwards dyed in a bath compoſed of the decoction of galls and madder mixed together, acquires a fine deep *brown*. The method of varying the ſhades of linen and cotton will be readily conceived, after we have given an account of calico printing, which forms the ſubject of the next chapter.

* *Gubliche, Berthollet*, ii. 349.

CHAP. VI. OF CALICO PRINTING.

Calico Printing.

CALICO printing is the art of communicating different colours to particular ſpots or figures on the ſurface of cotton or linen cloth, while the reſt of the ſtuff retains its original whiteneſs.

467
Origin of calico printing.

This ingenious art ſeems to have originated in India, where we know it has been practiſed for more than 2000 years. Pliny indeed informs us, that the Egyptians were acquainted with calico printing; but a variety of circumſtances combine to render it more than probable that they borrowed it from India. The art has but lately been cultivated in Europe; but the enlightened induſtry of our manufacturers has already improved prodigiouſly upon the tedious proceſſes of their Indian maſters. No art has riſen to perfection with greater celerity: a hundred years ago it was ſcarcely known in Europe; at preſent, the elegance of the patterns, the beauty and permanency of the colours, and the expedition with which the different operations are carried on, are really admirable.

A minute detail of the proceſſes of calico printing would not only be foreign to the plan of this article, but of very little utility. To the artiſt the proceſſes are already known; an account of them therefore could give him no new information; while it would fatigue and diſappoint thoſe readers who wiſh to underſtand the principles of the art. We ſhall content ourſelves, therefore, with a ſhort view of theſe principles.

468
It conſiſts in applying mordants partially to cotton,

Calico printing conſiſts in impregnating thoſe parts of the cloth which are to receive a colour with a mordant, and then dyeing it as uſual with ſome dye ſtuff or other. The dye ſtuff attaches itſelf firmly only to that part of the cloth which has received the mordant. The whole ſurface of the cotton is indeed more or leſs tinged; but by waſhing it, and bleaching it for ſome days on the graſs with the wrong ſide uppermoſt, all the unmordanted parts reſume their original colour, while thoſe which have received the mordant retain it. Let us ſuppoſe, that a piece of white cotton cloth is to receive red ſtripes; all the parts where the ſtripes are to appear are penciled over with a ſolution of acetite of alumina. After this, the cloth is dyed in the uſual manner with madder. When taken out of the dyeing veſſel, it is all of a red colour; but by waſhing and bleaching, the madder leaves every part of the cloth white except the ſtripes impregnated with the acetite of alumina, which remain red. In the ſame manner, may yellow ſtripes, or any other wiſhed-for figure, be given to cloth, by ſubſtituting quercitron bark, weld, &c. for madder.

469
Which is afterwards dyed and bleached.

When different colours are to be given to different parts of the cloth at the ſame time, it is done by impregnating it with various mordants. Thus if ſtripes be drawn upon a cotton cloth with acetite of alumina, and other ſtripes with acetite of iron, and the cloth be afterwards dyed in the uſual way with madder and then waſhed and bleached, it will be ſtriped *red* and *brown*. The ſame mordants with quercitron bark give *yellow*, and *olive* or *drab*.

470
Mordants employed.

The mordants employed in calico printing are acetite of alumina and acetite of iron, prepared in the manner deſcribed in the third chapter of this part. Theſe mordants are applied to the cloth, either with a pencil or by means of blocks, on which the pattern, according to which the cotton is to be printed, is cut. As they are applied only to particular parts of the cloth, care muſt be taken that none of them ſpread to the part of the cloth which is to be left white, and that they do not interfere with one another when more than one are applied.

Calico Printing.

applied. If these precautions be not attended to, all the elegance and beauty of the print must be destroyed. It is necessary, therefore, that the mordants should be of such a degree of consistence that they will not spread beyond those parts of the cloth on which they are applied. This is done by thickening them with flour or starch when they are to be applied by the block, and with gum arabic when they are to be put on with a pencil. The thickening should never be greater than is sufficient to prevent the spreading of the mordants; when carried too far, the cotton is apt not to be sufficiently saturated with the mordant; of course the dye takes but imperfectly.

471 How applied.

In order that the parts of the cloth impregnated with mordants may be distinguished by their colour, it is usual to tinge the mordants with some colouring matter or other. The printers commonly use the decoction of Brazil wood for this purpose; but Bancroft has objected to this method, because he thinks that the Brazil wood colouring matter impedes the subsequent process of dyeing. It is certain, that the colouring matter of the Brazil wood is displaced during that operation by the superior affinity of the dye stuff for the mordant. Were it not for this superior affinity, the colour would not take at all. Dr Bancroft * advises to co[lour] the mordant with some of the dye stuff afterwards to be applied; and he cautions the using of more for that purpose than is sufficient to make the mordant distinguishable when applied to the cloth. The reason of this precaution is obvious. If too much dye be mixed with the mordant, a great proportion of the mordant will be combined with colouring matter; which must weaken its affinity for the cloth, and of course prevent it from combining with it in sufficient quantity to ensure a permanent dye.

* Bancroft, ii. 375.

Sometimes these two mordants are mixed together in different proportions; and sometimes one or both is mixed with an infusion of sumach or of nut galls. By these contrivances, a great variety of colours are produced by the same dye stuff.

472 Subsequent treatment of the cloth

After the mordants have been applied, the cloth must be completely dried. It is proper for this purpose to employ artificial heat; which will contribute something towards the separation of the acetous acid from its base, and towards its evaporation; by which the mordant will combine in a greater proportion, and more intimately with the cloth.

When the cloth is sufficiently dried, it is to be washed with warm water and cow dung, till all the flour or gum employed to thicken the mordants, and all those parts of the mordants which are uncombined with the cloth, are removed. The cow dung serves to entangle these loose particles of mordants, and to prevent them from combining with those parts of the cloth which are to remain white. After this the cloth is thoroughly rinsed in clean water.

473 Dye stuffs used.

Almost the only dye stuffs employed by calico printers are, indigo, madder, and quercitron bark or weld. This last substance, however, is now but little used by the printers of this country, except for delicate greenish yellows. The quercitron bark has almost superseded it; because it gives colours equally good, and is much cheaper, and more convenient, not requiring so great a heat to fix it. Indigo, not requiring any mordant, is commonly applied at once either with the block or a pencil. It is prepared by boiling together indigo, potash made caustic by quicklime, and orpiment: the solution is afterwards thickened with gum (x). It must be carefully secluded from the air, otherwise the indigo would soon be regenerated, which would render the solution useless. Dr Bancroft has proposed to substitute coarse brown sugar for orpiment. It is equally efficacious in decomposing the indigo and rendering it soluble; while it likewise serves all the purposes of gum *.

* Bancroft, i. 120.

When the cloth, after being impregnated with the mordant, is sufficiently cleansed, it is dyed in the usual manner. The whole of it is more or less tinged with the dye stuff. It is well washed, and then spread out for some days on the grass, and bleached with the wrong side uppermost. This carries the colour off completely from all the parts of the cotton which has not imbibed the mordant, and leaves them of their original whiteness, while the mordanted spots retain the dye as strongly as ever.

Let us now give an example or two of the manner in which the printers give particular colours to calicoes. Some calicoes are only printed of one colour, others have two, others three, or more, even to the number of eight, ten, or twelve. The smaller the number of colours, the fewer in general are the processes.

474 Method of printing drabs.

1. One of the most common colours on cotton prints is a kind of nankeen yellow, of various shades, down to a deep yellowish brown or drab. It is usually in stripes or spots. To produce it, the printers besmear a block, cut out into the figure of the print, with acetite of iron thickened with gum or flour; apply it to the cotton; which, after being dried and cleaned in the usual manner, is plunged

(x) Different proportions are used by different persons. Mr Hauffman mixes 25 gallons of water with 16 pounds of indigo well ground (or a greater or smaller quantity, according to the quality of the indigo and the depth of colour wanted); to which he adds 30 pounds of good carbonat of potash, placing the whole over a fire; and as soon as the mixture begins to boil, he adds, by a little at a time, 12 pounds of quick lime, to render the alkali caustic, by absorbing its carbonic acid. This being done, 12 pounds of red orpiment are also added to the mixture; which is then stirred, and left to boil for some little time, that the indigo may be perfectly dissolved; which may be known by its giving a yellow colour immediately upon being applied to a piece of white transparent glass. M. Oberkampf, proprietor of the celebrated manufactory at Jouy near Versailles, uses a third more of indigo; and others use different proportions, not only of indigo, but of lime, potash, and orpiment; which all seem to answer with nearly equal success: but with the best copper-coloured Guatamala indigo, it is certain that a good blue may be obtained from only half the quantity prescribed by Mr Hauffman, by using as much stone, or oyster shell lime, as of indigo, nearly twice as much potash, and a fourth part less of orpiment than of indigo. See *Bancroft*, I. 113.

Calico Printing.

plunged into a potafs ley. The quantity of acetite of iron is always proportioned to the depth of the intended fhade.

475 Yellow, 2. For yellow, the block is befmeared with acetite of alumina. The cloth, after receiving this mordant, is dyed with quercitron bark, and then bleached.

476 Red, 3. Red is communicated by the fame procefs, only madder is fubftituted for the bark.

477 Blue, 4. The fine light blues, which appear fo often on printed cottons, are produced, by applying to the cloth a block befmeared with a compofition, confifting partly of wax, which covers all thofe parts of the cloth which are to remain white. The cloth is then dyed in a cold indigo vat; and after it is dry, the wax compofition is removed by means of hot water.

478 Lilac, brown, 5. Lilac, flea brown, and blackifh brown, are given by means of acetite of iron; the quantity of which is always proportioned to the depth of the fhade. For very deep colours, a little fumach is added. The cotton is afterwards dyed in the ufual manner with madder, and then bleached.

479 And dove. 6. Dove colour and drab, by acetite of iron and quercitron bark.

When different colours are to appear in the fame print, a greater number of operations are neceffary. Two or more blocks are employed, upon each of which

480 Application of different colours to the fame cloth. that part of the print only is cut which is to be of fome particular colour. Thefe are befmeared with different mordants, and applied to the cloth, which is afterwards dyed as ufual. Let us fuppofe, for inftance, that three blocks are applied to cotton; one with acetite of alumina, another with acetite of iron, a third with a mixture of thefe two mordants, and that the cotton is then dyed with quercitron bark, and bleached. The parts impregnated with the mordants would have the following colours.

Acetite of alumina, - - -	Yellow,
iron, - - -	Olive, drab, dove (L),
The mixture, - - - -	Olive green, olive.

If part of the yellow be covered over with the indigo liquor, applied with a pencil, it will be converted into *green*: By the fame liquid, blue may be given to fuch parts of the print as require it.

If the cotton be dyed with madder inftead of quercitron bark, the print will exhibit the following colours:

Acetite of alumina, - - -	Red,
iron, - - - -	Brown, black,
The mixture, - - - - -	Purple.

When a greater number of colours are to appear; for inftance, when thofe communicated by bark and thofe by madder are wanted at the fame time, mordants for part of the pattern are to be applied; the cotton is then to be dyed in the madder bath and bleached; then the reft of the mordants, to fill up the pattern, are added, and the cloth is again dyed with quercitron bark and bleached. This fecond dyeing does not much affect the madder colours; becaufe the mordants, which render them permanent, are already faturated. The yellow tinge is eafily removed by the fubfequent bleaching. Sometimes a new mordant is alfo applied to fome of the madder colours; in confequence of which they receive a new permanent colour from the bark. After the laft bleaching, new colours may be added by means of the indigo liquor. The following table will give an idea of the colours which may be given to cotton by thefe complicated proceffes.

I. *Madder dye.*	*Colours.*
Acetite of alumina, - - -	Red,
iron, - - - -	Brown, black,
Ditto diluted, - - - -	Lilac,
Both mixed, - - - - -	Purple.
II. *Bark dye.*	
Acetite of alumina, - - -	Yellow,
iron, - - - -	Dove, drab,
Lilac and acetite of alumina,	Olive,
Red and acetite of alumina,	Orange.
III. *Indigo dye.*	
Indigo, - - -	Blue,
Indigo and yellow - -	Green.

Thus no lefs than 12 colours may be made to appear together in the fame print by thefe different proceffes.

Thefe inftances will ferve to give the reader an idea of the nature of calico printing, and at the fame time afford an excellent illuftration of the importance of mordants in dyeing.

481 Colours for pencilling. If it were poffible to procure colours fufficiently permanent, by applying them at once to the cloth by the block or the pencil, as is the cafe with the mordants, the art of calico printing would be brought to the greateft poffible fimplicity: but at prefent this can only be done in one cafe, that of indigo; every other colour requires dyeing. Compofitions indeed may be made by previoufly combining the dye ftuff and the mordants. Thus *yellow* may be applied at once by employing a mixture of the infufion of quercitron bark and acetite of alumina; *red*, by mixing the fame mordant with the decoction of alumina, and fo on. Unfortunately the colours applied in this way are far inferior in permanency to thofe produced when the mordant is previoufly combined with the cloth, and the dye ftuff afterwards applied feparately. In this way are applied almoft all the fugitive colours of calicoes which wafhing or even expofure to the air deftroys.

As the application of colours in this way cannot always be avoided by calico printers, every method of rendering them more permanent is an object of importance. We fhall therefore conclude this chapter with a defcription of feveral colours of this kind propofed by Dr Bancroft, which have a confiderable degree of permanence.

A *yellow* printing colour may be formed by the following method: Let three pounds of alum, and three ounces of clean chalk, be firft diffolved in a gallon of hot water, and then add two pounds of fugar of lead; ftir this mixture occafionally during the fpace of 24 or 36 hours, then let it remain 12 hours at reft, and afterwards decant and preferve the clear liquor; this being

(L) According to the proportion of acetite of iron employed.

Calico Printing.

ing done, pour so much more warm water upon the remaining sediment, as after stirring and leaving the mixture to settle will afford clear liquor enough to make, when mixed with the former, three quarts of this aluminous mordant or acetite of alumine. Then take not less than six, nor more than eight, pounds of quercitron bark properly ground; put this into a tinned copper vessel, with four or five gallons of clean soft water, and make it boil for the space of one hour at least, adding a little more water, if at any time the quantity of liquor should not be sufficient to cover the surface of the bark: the liquor having boiled sufficiently, should be taken from the fire, and left undisturbed for half an hour, and then the clear decoction should be poured off through a fine sieve or canvas strainer. This being done, let six quarts more of clear water be poured upon the same bark and made to boil ten or fifteen minutes, both having been first well stirred; and being afterwards left a sufficient time to settle, the clean decoction may then be strained off, and put with the former into a shallow wide vessel to be evaporated by boiling, until what remains, being joined to the three quarts of aluminous mordant before mentioned, and to a sufficient quantity of gum or paste for thickening, will barely suffice to make three gallons of liquor in the whole. It will be proper, however, not to add the aluminous mordant, until the decoction is so far cooled as to be but little more than blood warm; and these being thoroughly mixed by stirring, may afterwards be thickened by the gum of Senegal or by gum arabic, if the mixture is intended for penciling; or by a paste made with starch or flour, if it be intended for printing.

By substituting a pound of murio sulphat of tin for the aluminous mordant in the above composition, a mixture may be formed which affords a very bright and full yellow, of considerable durability.

Sulphat of tin, mixed with a decoction of quercitron bark, communicates to cotton a *cinnamon* colour, which is sufficiently permanent *.

When the decoctions of quercitron bark and logwood are boiled together, and suitable proportions of sulphat of copper and of verdigris are added to them, with a little carbonat of potash, a compound is formed, which gives a *green* colour to cotton. Bancroft has made trial of this; and though it has not fully answered his expectation, his attempts were attended with sufficient success to determine him to persevere in his experiments †.

If acetite of iron be mixed with a decoction of quercitron bark, and the mixture be properly thickened, the compound will communicate to cotton a *drab* colour of some durability. This compound, mixed with the olive colouring liquor above described, will produce an olive. If a solution of iron, by a diluted muriatic acid, or by a diluted nitric acid, be employed for this purpose instead of iron liquor, it will produce colours a little more lasting; but these solutions should be employed sparingly, that they may not hurt the texture of the linen or cotton to which they are intended to be applied.

* *Bancroft*, i. 400.

† *Ibid*, 402.

Subtriple ‖ Sulphuret.

SUBTRIPLE, is when one quantity is the 3d part of another; as 2 is subtriple of 6. And *Subtriple Ratio* is the ratio of 1 to 3.

SUBTRIPLICATE RATIO, is the ratio of the cube roots. So the subtriplicate ratio of a to b, is the ratio of $\sqrt[3]{a}$ to $\sqrt[3]{b}$, or of $a^{\frac{1}{3}}$ to $b^{\frac{1}{3}}$.

SUCCESSION OF SIGNS, in astronomy, is the order in which they are reckoned, or follow one another, and according to which the sun enters them; called also *consequentia*. As Aries, Taurus, Gemini, Cancer, &c.

SULPHURET OF LIME having lately been recommended by an eminent chemist * as a substitute for *potash* in the new method of bleaching, which, if it answer, may certainly be afforded at less expence, we shall here give the method of preparing the sulphuret.

* *W. Higgins*, M. R. I. A.

Take of sulphur, or brimstone in fine powder, four pounds; lime, well slaked and sifted, twenty pounds; water, sixteen gallons: these are all to be well mixed and boiled for about half an hour in an iron vessel, stirring them briskly from time to time. Soon after the agitation of boiling is over, the solution of the sulphuret of lime clears, and may be drawn off free from the insoluble matter which is considerable, and which rests upon the bottom of the boiler (A). The liquor in this state is pretty nearly of the colour of small beer, but not quite so transparent.

Sulphuret ‖ Sun.

Sixteen gallons of fresh water are afterwards to be poured upon the insoluble dregs in the boiler, in order to separate the whole of the sulphuret from them. When this clears (being previously well agitated), it is also to be drawn off and mixed with the first liquor; to these again thirty-three gallons more of water may be added, which will reduce the liquor to a proper standard for steeping the cloth.

Here we have (an allowance being made for evaporation, and for the quantity retained in the dregs) sixty gallons of liquor from four pounds of brimstone.

Although sulphur by itself is not in any sensible degree soluble in water, and lime but very sparingly so, water dissolving but about one seven hundredth part of its weight of lime; yet the sulphuret of lime is highly soluble.

When the above proportion of lime and sulphur is boiled with only twelve gallons of water, the sulphuret partly crystallizes upon cooling; and when once crystallized it is not easy of solution.

SUN (see ASTRONOMY-*Index*, Encycl.) is certainly that celestial body which, of all others, should most attract our attention. It has accordingly employed much of

(A) Although lime is one of the constituent principles of the sulphuret, yet being so intimately united to the sulphur it has no longer the property of lime; upon the same principle that sulphuric acid in sulphat of potash has not the property of that acid.

of the time and meditation, not only of the aſtronomer, but alſo of the ſpeculative philoſopher, in all ages of the world; and many hypotheſes have been formed, and ſome diſcoveries made, reſpecting the nature and the uſes of this vaſt luminary.

Sir Iſaac Newton has ſhewn, that the ſun, by its attractive power, retains the planets of our ſyſtem in their orbits: he has alſo pointed out the method whereby the quantity of matter which it contains may be accurately determined. Dr Bradley has aſſigned the velocity of the ſolar light with a degree of preciſion exceeding our utmoſt expectation. Gallileo, Scheiner, Hevelius, Caſſini, and others, have aſcertained the rotation of the ſun upon its axis, and determined the poſition of its equator. By means of the tranſit of Venus over the diſk of the ſun, our mathematicians have calculated its diſtance from the earth, its real diameter and magnitude, the denſity of the matter of which it is compoſed, and the fall of heavy bodies on its ſurface. We have therefore a very clear notion of the vaſt importance and powerful influence of the ſun on its planetary ſyſtem; but with regard to its internal conſtruction, we are yet extremely ignorant. Many ingenious conjectures have indeed been formed on the ſubject; a few of which we ſhall mention as an introduction to Dr Herſchel's, of which, as it is the lateſt, and perhaps the moſt plauſible, we ſhall give a pretty full account nearly in his own words.

The dark ſpots in the ſun, for inſtance, have been ſuppoſed to be ſolid bodies revolving very near its ſurface. They have been conjectured to be the ſmoke of volcanoes, or the ſcum floating upon an ocean of fluid matter. They have alſo been taken for clouds. They were explained to be opaque maſſes ſwimming on the fluid matter of the ſun, dipping down occaſionally. It has been ſuppoſed that a fiery liquid ſurrounded the ſun, and that by its ebbing and flowing the higheſt parts of it were occaſionally uncovered, and appeared under the ſhape of dark ſpots; and that by the return of the fiery liquid, they were again covered, and in that manner ſucceſſively aſſumed different phaſes. The ſun itſelf has been called a globe of fire, though perhaps metaphorically. The waſte it would undergo by a gradual conſumption, on the ſuppoſition of its being ignited, has been ingeniouſly calculated; and in the ſame point of view its immenſe power of heating the bodies of ſuch comets as draw very near to it has been aſſigned.

In the year 1779 there was a ſpot on the ſun which was large enough to be ſeen with the naked eye. By a view of it with a ſeven feet reflector, charged with a very high power, it appeared to be divided into two parts. The largeſt of the two, on the 19th of April, meaſured 1′ 8″.06 in diameter, which is equal in length to more than 31,000 miles. Both together muſt certainly have extended above 50,000. The idea of its being occaſioned by a volcanic exploſion violently driving away a fiery fluid, ought to be rejected (ſays Dr Herſchel) on many accounts. "To mention only one, the great extent of the ſpot is very unfavourable to ſuch a ſuppoſition. Indeed a much leſs violent and leſs pernicious cauſe may account for all the appearances of the ſpot. When we ſee a dark belt near the equator of the planet Jupiter, we do not recur to earthquakes and volcanoes for its origin. An atmoſphere, with its natural changes, will explain ſuch belts. Our ſpot on the ſun may be accounted for on the ſame principles. The earth is ſurrounded by an atmoſphere compoſed of various elaſtic fluids. The ſun alſo has its atmoſphere; and if ſome of the fluids which enter into its compoſition ſhould be of a ſhining brilliancy, in the manner that will be explained hereafter, while others are merely tranſparent, any temporary cauſe which may remove the lucid fluid will permit us to ſee the body of the ſun through the tranſparent ones. If an obſerver were placed on the moon, he would ſee the ſolid body of the earth only in thoſe places where the tranſparent fluids of our atmoſphere would permit him. In others, the opaque vapours would reflect the light of the ſun without permitting his view to penetrate to the ſurface of our globe. He would probably alſo find, that our planet had occaſionally ſome ſhining fluids in its atmoſphere; as, not unlikely, ſome of our northern lights might not eſcape his notice, if they happened in the unenlightened part of the earth, and were ſeen by him in his long dark night. Nay, we have pretty good reaſon to believe, that probably all the planets emit light in ſome degree; for the illumination which remains on the moon in a total eclipſe cannot be entirely derived from the light which may reach it by the refraction of the earth's atmoſphere. For inſtance, in the eclipſe of the moon October 22. 1790, the rays of the ſun refracted by the atmoſphere of the earth towards the moon, admitting the mean horizontal refraction to be 30′ 50″.8, would meet in a focus 189,000 miles beyond the moon; ſo that conſequently there could be no illumination from rays refracted by our atmoſphere. It is, however, not improbable, that about the polar regions of the earth there may be refraction enough to bring ſome of the ſolar rays to a ſhorter focus. The diſtance of the moon at the time of the eclipſe would require a refraction of 54′ 6″, equal to its horizontal parallax at that time, to bring them to a focus ſo as to throw light on the moon.

The unenlightened part of the planet Venus has alſo been ſeen by different perſons; and not having a ſatellite, thoſe regions that are turned from the ſun cannot poſſibly ſhine by a borrowed light; ſo that this faint illumination muſt denote ſome phoſphoric quality of the atmoſphere of Venus.

In the inſtance of the large ſpot on the ſun already mentioned, Dr Herſchel concludes, from appearances, that he viewed the real body of the ſun itſelf, of which we rarely ſee more than its ſhining atmoſphere. In the year 1783 he obſerved a fine large ſpot, and followed it up to the edge of the ſun's limb. Here he took notice that the ſpot was plainly depreſſed below the ſurface of the ſun, and that it had very broad ſhelving ſides. He alſo ſuſpected ſome part, at leaſt, of the ſhelving ſides to be elevated above the ſurface of the ſun; and obſerved that, contrary to what uſually happens, the margin of that ſide of the ſpot which was fartheſt from the limb was the broadeſt.

The luminous ſhelving ſide of a ſpot may be explained by a gentle and gradual removal of the ſhining fluid, which permits us to ſee the globe of the ſun. As to the uncommon appearance of the broadeſt margin being on that ſide of the ſpot which was fartheſt from the limb when the ſpot came near the edge of it, we may ſurmiſe that the ſun has inequalities on its ſurface, which Sun.

Sun.

may possibly be the cause of it. For when mountainous countries are exposed, if it should chance that the highest parts of the landscape are situated so as to be near that side of the margin or penumbra of the spot which is towards the limb, they may partly intercept our view of it when the spot is seen very obliquely. This would require elevations at least five or six hundred miles high; but considering the great attraction exerted by the sun upon bodies at its surface, and the slow revolution it has upon its axis, we may readily admit inequalities to that amount. From the centrifugal force at the sun's equator, and the weight of bodies at its surface, he computes, that the power of throwing down a mountain by the exertion of the former, balanced by the superior force of keeping it in its place of the latter, is near 6½ times less on the sun than on our equatorial regions; and as an elevation similar to one of three miles on the earth would not be less than 334 miles on the sun, there can be no doubt but that a mountain much higher would stand very firmly. The little density of the solar body seems also to be in favour of the height of its mountains; for, *cæteris paribus*, dense bodies will sooner come to their level than rare ones. The difference in the vanishing of the shelving side, instead of explaining it by mountains, may also, and perhaps more satisfactorily, be accounted for from the real difference of the extent, the arrangement, the height, and the intensity of the shining fluid, added to the occasional changes that may happen in these particulars during the time in which the spot approaches to the edge of the disk. However, by admitting large mountains on the face of the sun, we shall account for the different opinions of two eminent astronomers; one of whom believed the spots depressed below the surface of the sun, while the other believed them elevated above it. For it is not impossible that some of the solar mountains may be high enough occasionally to project above the shining elastic fluid, when, by some agitation or other cause, it is not of the usual height; and this opinion is much strengthened by the return of some remarkable spots which served Cassini to ascertain the period of the sun's rotation. A very high country, or chain of mountains, may oftener become visible, by the removal of the obstructing fluid, than the lower regions, on account of its not being so deeply covered with it.

In 1791 the Doctor examined a large spot on the sun, and found it evidently depressed below the level of the surface. In 1792 he examined the sun with several powers from 90 to 500, when it appeared evidently, that the black spots are the opaque ground, or body of the sun; and that the luminous part is an atmosphere, which, being interrupted or broken, gives us a transient glimpse of the sun itself. He perceived likewise, that the shining surface of the sun is unequal, many parts of it being elevated and others depressed; and that the elevations, to which Hevelius gave the name of *faculæ*, so far from resembling torches, were rather like the shrivelled elevations upon a dried apple, extended in length, and most of them joined together, making waves or waving lines. The faculæ being elevations, very satisfactorily explains the reason why they disappear towards the middle of the sun, and reappear on the other margin; for about the place where we lose them, they begin to be edgewise to our view; and if between the faculæ should lie dark spots, they will most frequently break out in the middle of the sun, because they are no longer covered by the side-views of these faculæ.

The Doctor gives a very particular account of all his observations, which seem to have been accurately made, and we need scarcely add with excellent telescopes. For that account, however, we must refer to the memoir itself, and hasten to lay before our readers the result of his observations. "That the sun (says he) has a very extensive atmosphere, cannot be doubted; and that this atmosphere consists of various elastic fluids, that are more or less lucid and transparent, and of which the lucid one is that which furnishes us with light, seems also to be fully established by all the phenomena of its spots, of the faculæ, and of the lucid surface itself. There is no kind of variety in these appearances but what may be accounted for with the greatest facility, from the continual agitation which, we may easily conceive, must take place in the regions of such extensive elastic fluids.

"It will be necessary, however, to be a little more particular as to the manner in which I suppose the lucid fluid of the sun to be generated in its atmosphere. An analogy that may be drawn from the generation of clouds in our own atmosphere, seems to be a very proper one, and full of instruction. Our clouds are probably decompositions of some of the elastic fluids of the atmosphere itself, when such natural causes, as in this grand chemical laboratory are generally at work, act upon them: we may therefore admit, that in the very extensive atmosphere of the sun, from causes of the same nature, similar phenomena will take place; but with this difference, that the continual and very extensive decompositions of the elastic fluids of the sun are of a phosphoric nature, and attended with lucid appearances, by giving out light.

"If it should be objected, that such violent and unremitting decompositions would exhaust the sun, we may recur again to our analogy, which will furnish us with the following reflections. The extent of our own atmosphere, we see, is still preserved, notwithstanding the copious decompositions of its fluids in clouds and falling rain; in flashes of lightning, in meteors, and other luminous phenomena; because there are fresh supplies of elastic vapours continually ascending to make good the waste occasioned by those decompositions. But it may be urged, that the case with the decomposition of the elastic fluids in the solar atmosphere would be very different, since light is emitted, and does not return to the sun, as clouds do to the earth when they descend in showers of rain. To which I answer, that, in the decomposition of phosphoric fluids, every other ingredient but light may also return to the body of the sun. And that the emission of light must waste the sun, is not a difficulty that can be opposed to our hypothesis: for as it is an evident fact that the sun does emit light, the same objection, if it could be one, would equally militate against every other assignable way to account for the phenomenon.

"There are, moreover, considerations that may lessen the pressure of this alleged difficulty. We know the exceeding subtilty of light to be such, that in ages of time its emanation from the sun cannot very sensibly lessen the size of this great body. To this may be added, that very possibly there may always be ways of restoration to compensate for what is lost by the emission

Sun.

fion of light, though the manner in which this can be brought about fhould not appear to us. Many of the operations of Nature are carried on in her great laboratory which we cannot comprehend, but now and then we fee fome of the tools with which fhe is at work. We need not wonder that their conftruction fhould be fo fingular as to induce us to confefs our ignorance of the method of employing them; but we may reft affured that they are not a mere *lufus naturæ*." Here he alludes to the great number of fmall telefcopic comets; which he fuppofes, as others had done before him, may be employed to reftore to the fun what had been loft by the emiffion of light. "My hypothefis, however, (continues he) does not lay me under any obligation to explain how the fun can fuftain the wafte of light. nor to fhew that it will fuftain it for ever; and I fhould alfo remark that, as in the analogy of generating clouds, I merely allude to their production as owing to a decompofition of fome of the elaftic fluids of our atmofphere, that analogy, which firmly refts upon the fact, will not be lefs to my purpofe, to whatever caufe thefe clouds may owe their origin. It is the fame with the lucid clouds, if I may fo call them, of the fun. They plainly exift, becaufe we fee them; the manner of their being generated may remain an hypothefis—and mine, till a better can be propofed, may ftand good; but whether it does or not, the confequences I am going to draw from what has been faid will not be affected by it."

Before he proceeds to draw thefe confequences, he informs us that, according to the above theory, a dark fpot in the fun is a place in its atmofphere, which happens to be free from luminous decompofitions; that faculæ are, on the contrary, more copious mixtures of fuch fluids as decompofe each other; and that the regions, in which the luminous folar clouds are formed, adding thereto the elevation of the faculæ, cannot be lefs than 1843, nor much more than 2765 miles in depth. It is true, continues he, that in our atmofphere the extent of the clouds is limited to a very narrow compafs; but we ought rather to compare the folar ones to the luminous decompofitions which take place in our *aurora borealis*, or luminous arches, which extend much farther than the cloudy regions. The denfity of the luminous folar clouds, though very great, may not be exceedingly more fo than that of our *aurora borealis*. For if we confider what would be the brilliancy of a fpace two or three thoufand miles deep, filled with fuch corrufcations as we fee now and then in our atmofphere, their apparent intenfity, when viewed at the diftance of the fun, might not be much inferior to that of the lucid folar fluid.

From the luminous atmofphere of the fun, he proceeds to its opaque body; which, by calculation from the power it exerts upon the planets, we know to be of great folidity; and from the phenomena of the dark fpots, many of which, probably on account of their high fituations, have been repeatedly feen, and otherwife denote inequalities in their level, we furmife that its furface is diverfified with mountains and valleys.

What has been faid, enables us to come to fome very important conclufions, by remarking, that this way of confidering the fun and its atmofphere removes the great diffimilarity we have hitherto been ufed to find between its condition and that of the reft of the great bodies of the folar fyftem.

The fun, viewed in this light, appears to be nothing elfe than a very eminent, large, and lucid planet, evidently the firft, or, in ftrictnefs of fpeaking, the only primary one of our fyftem, all others being truly fecondary to it. Its fimilarity to the other globes of the folar fyftem with regard to its folidity, its atmofphere, and its diverfified furface, the rotation upon its axis, and the fall of heavy bodies, leads us on to fuppofe that it is moft probably alfo inhabited, like the reft of the planets, by beings whofe organs are adapted to the peculiar circumftances of that vaft globe.

It may, however, not be amifs to remove a certain difficulty, which arifes from the effect of the fun's rays upon our globe. The heat which is here, at the diftance of 95 millions of miles, produced by their rays, is fo confiderable, that it may be objected, that the furface of the globe of the fun itfelf muft be fcorched up beyond all conception.

This may be very fubftantially anfwered by many proofs drawn from natural philofophy, which fhew that heat is produced by the fun's rays only when they act upon a calorific medium; they are the caufe of the production of heat, by uniting with the matter of fire which is contained in the fubftances that are heated; as the collifion of flint and fteel will inflame a magazine of gunpowder, by putting all the latent fire it contains into action. But an inftance or two of the manner in which the folar rays produce their effect, will bring this home to our moft common experience.

On the tops of mountains of a fufficient height, at an altitude where clouds can very feldom reach to fhelter them from the direct rays of the fun, we always find regions of ice and fnow. Now if the folar rays themfelves conveyed all the heat we find on this globe, it ought to be hotteft where their courfe is leaft interrupted. Again, our aëronauts all confirm the coldnefs of the upper regions of the atmofphere; and fince, therefore, even on our earth, the heat of any fituation depends upon the aptnefs of the medium to yield to the impreffion of the folar rays, we have only to admit, that on the fun itfelf, the elaftic fluids compofing its atmofphere, and the matter on its furface, are of fuch a nature as not to be capable of any exceffive affection from its own rays: and indeed this feems to be proved by the copious emiffion of them; for if the elaftic fluids of the atmofphere, or the matter contained on the furface of the fun, were of fuch a nature as to admit of an eafy chemical combination with its rays, their emiffion would be much impeded.

Our author then proceeds to fupport his theory by analogical reafonings; but as thefe will occur to fuch of our readers as are converfant with the fpeculations of aftronomers, we pafs on to his reflections upon the confequences of this theory. "That the ftars are funs can hardly admit of a doubt. Their immenfe diftance would perfectly exclude them from our view, if the light they fend us were not of the folar kind. Befides, the analogy may be traced much farther. The fun turns on its axis; fo does the ftar Algol; fo do the ftars called β Lyræ, δ Cephei, η Antinoi, ο Ceti, and many more; moft probably all. From what other caufe can we fo probably account for their periodical changes? Again,

our sun has spots on its surface; so has the star Algol, and so have the stars already noticed, and probably every star in the heavens. On our sun these spots are changeable; so they are on the star Ceti, as evidently appears from the irregularity of its changeable lustre, which is often broken in upon by accidental changes while the general period continues unaltered. The same little deviations have been observed in other periodical stars, and ought to be ascribed to the same cause. But if stars are suns, and suns are inhabitable we see at once what an extensive field for animation opens itself to our view.

"It is true, that analogy may induce us to conclude, that since stars appear to be suns, and suns, according to the common opinion, are bodies that serve to enlighten, warm, and sustain a system of planets, we may have an idea of numberless globes that serve for the habitation of living creatures. But if these suns themselves are primary planets, we may see some thousands of them with our own eyes, and millions by the help of telescopes, when at the same time the same analogical reasoning still remains in full force with regard to the planets which these suns may support."

The Doctor then observes, that from other considerations, the idea of suns or stars being *merely* the supporters of systems of planets, is not absolutely to be admitted as a general one. "Among the great number of very compressed clusters of stars I have given (says he) in my catalogues, there are some which open a different view of the heavens to us. The stars in them are so very close together, that, notwithstanding the great distance at which we may suppose the cluster itself to be, it will hardly be possible to assign any sufficient mutual distance to the stars composing the cluster, to leave room for crowding in those planets, for whose support these stars have been, or might be, supposed to exist. It should seem, therefore, highly probable, that they exist for themselves; and are, in fact, only very capital, *lucid*, primary planets, connected together in one great system of mutual support.

"The same remark may be made with regard to the number of very close double stars, whose apparent diameters being alike, and not very small, do not indicate any very great mutual distance: from which, however, must be deducted all those where the different distances may be compensated by the real difference in their respective magnitudes.

"To what has been said may be added, that, in some parts of the milky way, where yet the stars are not very small, they are so crowded, that in the year 1792, Aug. 22. I found by the gauges that, in 41 minutes of time, no less than 258,000 of them had passed through the field of view of my telescope.

"It seems, therefore, upon the whole, not improbable, that in many cases stars are united in such close systems as not to leave much room for the orbits of planets or comets; and that consequently, upon this account also, many stars, unless we would make them mere useless brilliant points, may themselves be lucid planets, perhaps unattended by satellites."

What a magnificent idea does this theory give of the universe, and of the goodness, as well as power, of its Author? And how cold must be that heart, and clouded that understanding, who, after the contemplation of it, can for one moment listen to the atheistical doctrines of those men who presume to account for all the phenomena of nature by chemical affinities and mechanical attraction? The man who, even in his heart, can say, that such an immense system, differing so widely in the structure of the different parts of it, but everywhere crowded with life, is the effect of unintelligent agency, is indeed, to use the emphatic language of an ancient astronomer—*a fool*.

Sunda
||
Sutton.

SUNDA, Straits of, are formed by the approach of the south-east extremity of the island of Sumatra to the north west extremity of the island of Java (See these islands, *Encycl.*). The straits are interspersed with a number of small isles; the whole displaying a scenery scarcely to be exceeded in the softness, richness, and gaiety of its appearance. The two great islands, which are low, and in some places marshy near the shore, rise afterwards, in a gradual slope, towards the interior of the country, admitting in their ascent every variety of situation, and all the different tints of verdure. Of the smaller islands, a few have steep and naked sides, such as one in the middle of the strait, which the English navigators have distinguished, on that account, by the name of Thwart-the way, and two very small round ones, called, from their figures, the Cap and Button (see these islands, *Suppl.*); but most of the others are entirely level, founded upon beds of coral, and covered with trees. Some of these islands are surrounded with a white sandy beach, visited frequently by turtle; but most of them are adorned with thick shrubbery to the water's edge, the roots being washed by the sea, or the branches dipping into it; and on the outside are shoals, in which a multitude of little aquatic animals are busied in framing calcareous habitations for their residence and protection. Those fabrics gradually emerge above the surface of the water, and at length, by the adventitious adhesion of vegetable matter, giving birth to plants and trees, become new islands, or add to the size of those already produced by the same means. It is impossible not to be struck with the diversified operations of Nature for obtaining the same end, whether employed in originally fixing the granite foundation of the Brazils, or in throwing up, by some sudden and subsequent convulsion, the island of Amsterdam, or in continuing to this hour, through the means of animated beings, the formation of new lands in the Straits of Sunda. *Sir George Staunton's Account of the British Embassy to China.*

SUNNUD, a grant, patent, or charter, in Bengal.

SUPERPARTICULAR Proportion, or Ratio, is that in which the greater term exceeds the less by unit or 1. As the ratio of 1 to 2, or 2 to 3, or 3 to 4, &c.

SUPERPARTIENT Proportion, or Ratio, is when the greater term contains the less term once, and leaves some number greater than 1 remaining. As the ratio

of 3 to 5, which is equal to that of 1 to $1\frac{2}{3}$;

of 7 to 10, which is equal to that of 1 to $1\frac{3}{7}$; &c.

SUPPLEMENT, of an Arch or Angle, in geometry or trigonometry, is what it wants of a semicircle, or of 180°; as the *complement* is what it wants of a quadrant, or of 90°. So, the supplement of 50° is 130°; as the complement of it is 40°.

SUTTON (Thomas, Esq.), founder of the charter-house, was born at Knaith in Lincolnshire, in 1532, of an

Sutton.

an ancient and genteel family. He was educated at Eton school, and probably at Cambridge, and studied the law in Lincoln's Inn; but this profession not suiting his disposition, he travelled into foreign countries, and made so long a stay in Holland, France, Spain, and Italy, as to acquire the languages of those various nations. During his absence, his father died, and left him a considerable fortune. On his return home, being a very accomplished gentleman, he became secretary to the earl of Warwick and his brother the earl of Leicester. By the former of these noblemen, in 1569, he was appointed master of the ordnance at Berwick; and distinguishing himself greatly in that situation, on the rebellion which at that time broke out in the north, he obtained a patent for the office of master general of the ordnance for that district for life. He is named as one of the chiefs of those 1500 men who marched into Scotland, by the order of Queen Elizabeth, to the assistance of the regent, the earl of Morton, in 1573; and he commanded one of the five batteries which obliged the strong castle of Edinburgh to surrender to the English. He purchased of the bishop of Durham the manors of Gateshead and Wickham; which, producing coal-mines, became to him a source of extraordinary wealth. In 1580, he was reputed to be worth L. 50,000

Soon after this, he married a rich widow, who brought him a considerable estate; and taking up the business of a merchant, riches flowed in to him with every tide. He is said to have had no less than thirty agents abroad. He was likewise one of the chief victuallers of the navy; and seems to have been master of the barque called Sutton, in the list of volunteers attending the English fleet against the Spanish armada. It is probable, also, that he was a principal instrument in the defeat of it, by draining the bank of Genoa of that money with which Philip intended to equip his fleet, and thereby hindering the invasion for a whole year. He is likewise said to have been a commissioner for prizes under Lord Charles Howard, High Admiral of England; and going to sea with letters of marque, he took a Spanish ship worth L. 20,000. His whole fortune, at his death, appears to have been in land L. 5,000 *per annum*; in money, upwards of L. 60,000; the greatest estate in the possession of any private gentleman till much later times He lived with great munificence and hospitality: but losing his lady in 1602, he retired from the world, lessened his family, and lived in a private frugal manner; and, having no issue, resolved to distinguish his name by some important charity. Accordingly, he purchased of the Earl of Suffolk Howard-House, or the late dissolved charter house, near Smithfield for the sum of L. 13,000, where he founded the present hospital, in 1611, for the relief of poor men and children. Before he had fixed upon this design, the court endeavoured to divert him from his purpose, and to engage him to make Charles I. then Duke of York his heir, by conferring on him a peerage; but being free from ambition, and now near his grave, the lustre of the coronet could not tempt him to change his plan. He died the 11th of December, 1611, at Hackney, aged 79. His body was conveyed, with the most solemn procession, to Christ church in London and there deposited, till 1614, when it was removed to the charter house, and interred in a vault on the north side of the chapel, under a magnificent tomb.

SUWOROW (A) RIMNIKSKI (Count Alexander), was a man so eminent in his profession, that, if war be an art founded on science, it would be improper not to give some account of his life in a Work of this nature. Various accounts of him, indeed, are already in the hands of the public; but they differ so much from one another in the pictures which they present of the *man*, that it is not easy, if it be always possible, to distinguish truth from falsehood. With respect to the talents of the *General*, there is not room for the same difference of representation; because a train of military successes, almost unrivalled, has rendered these conspicuous to all Europe. In the short detail that our limits permit us to give of the life of this singular man, we shall avail ourselves of all the information, public and private, which we have been able to obtain, and believe to be authentic; and we hope to make our readers acquainted with some particulars respecting his person and domestic habits which are not yet generally known.

The family of Suworow is said to have been from Sweden, and of a noble descent. The first of this name settled in Russia about the latter end of the last century; and having engaged in the wars against the Tartars and the Poles, were rewarded by the Czars of that period with lands and peasants. Basil, the father of our hero, is said to have been the godson of Peter the Great; to have been held in high estimation for his political knowledge and extensive erudition; and to have enjoyed, at his death, the two-fold rank of General and Senator *.

As this account is given by a man who professes to have formed an intimate acquaintance with Suworow himself, it ought to be correct; and yet we cannot help entertaining some doubts of its truth, or at least of its accuracy. It is well known, that extensive erudition was in no esteem in Russia at the period when Basil Suworow is here said to have been so learned; and it is likewise known, that if, by erudition, be meant a knowledge of ancient literature, it was even despised, at a much later period, by all who were at once noble, and possessed of lands and peasants (See RUSSIA, *Encycl.*). The truth is, as we have learned from unquestionable authority, that the family of Suworow was ancient and respectable; but being far from affluent, and their little property lying at the very extremity of the empire, we have reason to believe, that the subject of this memoir was the first of the family that ever was at court. Basil, however, if his ancestors were from Sweden, may have been free from the Russian prejudices against Greek and Latin; and this is the more probable, that he certainly gave a learned education to his son.

That son, Alexander Basilowitch Suworow, was according to the author already quoted, born in the year 1730;

(A) This name is spelled sometimes as we have spelled it, sometimes SUWARROW, and sometimes SUVOROFF. This last is according to the pronunciation; but we have adopted the orthography of the General himself, in his letter to Charette, the hero of Vendee.

1730: we have ſome reaſon to believe, that he was not born before 1732. His father had deſtined him, we are told, for the robe; but his early inclinations impelled him to the profeſſion of a ſoldier; and in 1742 he was enrolled as a fuſilier in the guards of Seimonow. He was afterwards a corporal, then a ſerjeant, and in 1754, he quitted the guards with the brevet of Lieutenant in the army. He made his firſt campaign in the ſeven years war againſt the Pruſſians, in the year 1759, entering upon actual ſervice under Prince Wolgonſki. As ſenior officer on duty, he attended on the commander in chief Count Fermor, who, admiring the conſummate reſolution which he appeared to poſſeſs, favoured him with his particular confidence. In 1761, he was ordered on ſervice in the light troops under General Berg; and with the rank of a field officer (we think that of Lieutenant colonel) he performed prodigies of valour, and exhibited much of that character which was afterwards ſo fully developed and diſplayed. Even then he ſeems to have formed the reſolution of dying on the field of battle rather than ſuffer himſelf to be taken priſoner; for when, with a handful of troops, he was once ſurrounded by a large detachment of Pruſſians, he determined to cut his way through them, or periſh in the attempt. In this daring enterpriſe he was not only ſucceſsful, but contrived to carry off with him twenty priſoners, though he was obliged to abandon two field-pieces, which he had a little before taken from a ſmaller detachment.

At the peace of 1762, he received from the Empreſs a colonel's commiſſion, written with her own hand; and being advanced, in 1768, to the rank of brigadier, he was, in the month of November, ordered to repair, with all poſſible ſpeed, to the frontiers of Poland. At that unfavourable ſeaſon, he croſſed rivers and moraſſes, whoſe paſſage was rendered more difficult by ſlight froſts; and, in the courſe of a month, traverſed 500 Engliſh miles, with the loſs of only a few men in the environs of Smolenſko.

The object of the Empreſs, at this time, was to ſubdue the Poliſh confederates, and to poſſeſs herſelf of certain provinces of that ill fated kingdom. How completely ſhe and her two allies, the Emperor of Germany and the King of Pruſſia, ſucceeded in their enterpriſe, has been related elſewhere (ſee POLAND, *Encycl.*). It is ſufficient, in this memoir, to obſerve, that the ſucceſſes of the Ruſſians were chiefly owing to the military ſkill and intrepidity of Suworow, who was their only active General, and was indeed, for four years, almoſt conſtantly employed in offenſive operations againſt the confederates. Not to mention the numerous actions and ſkirmiſhes of an inferior kind, in which his conduct and courage were always diſplayed, the victory at Stalovitz, over a ſuperior force, ably commanded, and the capture of Cracow, were alone ſufficient to intitle him to the character which he ever afterwards ſo well ſupported. The former of theſe drew the higheſt encomiums from the great Frederick of Pruſſia; and the latter decided the fate of Poland. It is proper to add, that Suworow, on theſe occaſions, did not tarniſh his laurels by unneceſſary cruelty. When a French officer, who ſurrendered at Cracow, offered him his ſword, according to the cuſtom of war, he refuſed it, ſaying, that he would not take the ſword of a brave man, whoſe maſter was not at war with his ſovereign; and, even to the leaders of the confederates, he granted better terms of capitulation than they had the preſumption to aſk.

In the year 1770, he had been promoted to the rank of Major general; and for his exploits in the Poliſh war, the Empreſs conferred upon him, at different times, the orders of St Ann, St George, and Alexander Newſky.

After performing ſome important ſervices on the frontiers of Sweden, Suworow received orders, in the beginning of 1773, to join the army in Moldavia, under the command of Field marſhal Romanzow; and there he began that glorious career, which ſoon made his name a terror to the Turks. His firſt exploit was the taking of Turtukey; of which he wrote the following laconic account to the commander in chief:

"Honour and glory to God! Glory to you, Romanzow! We are in poſſeſſion of Turtukey, and I am in it! "SUWOROW."

During the remainder of the war, which was of ſhort continuance, Suworow was conſtantly engaged, and conſtantly ſucceſsful. In the beginning of the year 1774, he was promoted to the rank of Lietenant-general; and on the 11th of June of the ſame year, he defeated the Turks in a great battle, in which they loſt 3000 men killed, ſome hundreds of priſoners, 40 pieces of artillery, and 80 ſtandards, with their ſuperb camp. Soon after this victory, peace was concluded between the two courts; and Lieutenant-general Suworow was ordered to proceed with all poſſible haſte to Moſcow, to aſſiſt in appeaſing the interior troubles of that part of the empire.

Theſe troubles were occaſioned by a Coſſac rebel, of the name of *Pugatchew*, or *Pugatcheff*, who, at the head of a party of his diſcontented countrymen, had long eluded the vigilance of Count Panin, the commander in chief in Muſcovy, and frequently cut off detachments of the army which were ſent out in queſt of him. The chace of Pugatcheff, for ſuch it may be called, was now wholly entruſted to the well-known activity of Suworow; and that General, after purſuing the rebel with inconceivable rapidity, through woods and deſerts, came up with him at a place called Urlaſk, and carried him priſoner to Count Panin, who ſent him to Moſcow, where he ſuffered the puniſhment due to his crimes. This inſurgent, it is ſaid, had at one time collected ſuch a force, and was followed with ſuch enthuſiaſm, that, if his underſtanding had been equal to his courage, and his moderation had kept pace with his power, he might have poſſeſſed himſelf of Moſcow, and made the Imperial Catharine tremble on her throne.

For ſeveral years after the taking of Pugatcheff, Suworow was employed in the Crimea, on the Cuban, and againſt the Nogay Tartars, in a kind of ſervice which, though it was of the utmoſt importance to the Empreſs, and required all the addreſs of the Lieutenant-general, furniſhed no opportunities for that wonderful diſplay of promptitude and reſource, which had characteriſed his more active campaigns. One incident, however, muſt be mentioned, even in this ſhort memoir, becauſe it ſhews the natural diſpoſition of the man. During the winter that Suworow paſſed among the Tartars, he was frequently viſited by the chiefs of that nation; and at one of theſe viſits, Mechmed Bay, the chief of the Gediſſens, often joked with Muſſa Bay, another chief, on his inclination to marry. Muſſa Bay

Suworow. was so extremely old, that Suworow thought the conversation ridiculous; and one day asked him, What ground Mechmed could have for such idle talk? Mussa replied, that Mechmed Bey was right; that he wished to marry; and that he hoped the General would make him a present of a beautiful Tartar girl of sixteen! Suworow immediately bought a young Tartar slave of a Cossac for 100 rubles, and sent her to Mussa Bey; who married her, lived with her a very few years, and died at the age of one hundred and eight! regretted, we are told, by the Lieutenant-general, who regarded him with great esteem and attachment.

In the end of the year 1786, Suworow was promoted to the rank of General in Chief; and, at the breaking out of the war with the Turks in 1787, he shewed how well he was intitled to that rank, by his masterly defence of Kinburn; a place of no strength, but of great importance, as it is situated at the mouth of the Dneiper, opposite to Oczakow. For the zeal and abilities which he displayed on this occasion, the Empress decorated him with the order of St Andrew; gave him six crosses of the order of St George, to be distributed, according to his judgment, among such of his officers as had most distinguished themselves; and, in a very flattering letter, regretted the wounds which he had received in defending the place.

At the siege of Oczakow, Suworow, who commanded the left wing of the army under Prince Potemkin, received a dangerous wound in the nape of the neck, which was followed by so smart a fever, that, for some time, his life was despaired of; but he persevered in his long accustomed practice of preferring regimen to medicine, and his health was gradually re-established. In the year 1789, he was appointed to the command of the army which was to co-operate with the Prince of Saxe Cobourg in Walachia; and, by marches of inconceivable rapidity, he twice, in the space of two months, preserved the army of that Prince from inevitable destruction. Putting himself at the head of 8000 Russians, and literally running to the aid of his ally, he came up with the Turks in time to change the fate of the day at the battle of Forhani, which was fought on the 21st of July; and again at Rymnik, which, with 7000 men, he had reached with equal celerity, he gained, on the 22d of September, in conjunction with the Prince, one of the greatest victories that have ever been atchieved. According to the least exaggerated account, the Turkish army, commanded by the Grand Visier in person, amounted to 90,000 or 100,000 men; of which 70,000 were chosen troops: whilst the army of the allies exceeded not 25,000. At the commencement of the attack, Suworow, who had reconnoitered the country, and formed the plan of the battle, called out to his Russians, "My friends, look not at the eyes of your enemies, but at their breasts; it is there that you must thrust your bayonets." No quarter was given to the Turks; and on this account the Russian General has been charged with savage ferocity: but the charge, if not groundless, must be shared equally between him and the Prince of Cobourg. The commanders of the allied army, aware of the immense superiority of their enemies, had resolved, before the engagement, not to encumber themselves with prisoners, whom they could not secure without more than hazarding the fate of the day: And where is the man, who admits the lawfulness of war, that will condemn such conduct in such critical circumstances?

The taking of Bender and Belgrade were the immediate consequences of the victory of Rymnik; and so sensible was the Emperor Joseph how much the rapid movements and military skill of Suworow had contributed to that victory, that he immediately created him a Count of the Roman empire, and accompanied the diploma with a very flattering letter. Similar honours were conferred upon him by his own sovereign, who sent him the diploma of Count of the empire of Russia, with the title of Rymnikski, and the order of St Andrew of the first class.

In the autumn of 1790, Prince Potemkin wrote to Count Suworow, requesting a particular conference. The General, who conjectured the object of it, sent him the following answer: "The flotilla of row-boats will get possession of the mouths of the Danube; Tulcia and Isaccia will fall into our power; our troops, supported by the vessels, will take Ismailow and Brahilow, and make Tchistow tremble." He was perfectly right in his conjecture: it was to concert with him measures for the taking of Ismailow that the Prince had requested the conference. He did not, however, receive orders to undertake that desperate enterprise till the beginning of November, when he rapidly approached towards that fortress. His army, by sea and land, consisted of 23,000 men; of whom one-half were Cossacs, and of these many were sick. The troops of the garrison, which were under the orders of seven Sultans, amounted to 43,000 men, of whom nearly one half were Janissaries; the fortress was by much the strongest of any on the Turkish frontier; it was under the command of an old warrior, who had twice refused the dignity of Grand Visier, and had displayed against the Austrians considerable abilities, as well as the most intrepid courage; and the Grand Seignior had published a firman, forbidding the garrison, on pain of death without trial, to surrender on any terms whatever.

Potemkin, knowing that Suworow had with him no battering cannon, and dreading the consequences of a repulse, wrote to the General, that if he was not certain of success, he would do well not to risk an assault. The laconic reply was; "My plan is fixed. The Russian army has already been twice at the gates of Ismailow; and it would be shameful to retreat from them the third time without entering the place." To spare the effusion of blood, however, if possible, he sent a note to the Seraskier who commanded in Ismailow, to assure him, upon Count Suworow's word of honour, that if he did not hang out a white flag that very day, the place would be taken by assault, and all the garrison put to the sword. The Seraskier returned no answer to the note; but another commander was pleased to say, that "The Danube would cease to flow, or the heavens bow down to the earth, before Ismailow would surrender to the Russians!"

Having concerted with the Admiral proper measures for the assault, Suworow passed the night, with some officers of his suite, in impatient vigilance for the appointed hour when the signals were to be given. These were the firing of a musket at three, four, and five in the morning, when the army rushed upon the place; and notwithstanding the desperate opposition of the Turks, the depth of the moat, and the height of the ramparts,

ramparts, they were completely masters of Ismailow by four o'clock P. M. In this one dreadful day the Ottomans lost 33,000 men killed or dangerously wounded; 10,000 who were taken prisoners; besides 6000 women and children, and 2000 Christians of Moldavia, who fell in the general massacre. The place was given up to plunder for three days, according to agreement with the army before the assault; but we have authority to say, that no person was murdered in cold blood, who did not prefer his property to his life.

The Russians found in Ismailow 232 pieces of cannon, many large and small magazines of gunpowder, an immense quantity of bombs and ball, 345 standards almost all stained with blood, provisions for the Turkish army for six months, and about 10,000 horses, of which many were extremely beautiful. Suworow, who was inaccessible to any views of private interest, did not appropriate to himself a single article, not so much as a horse; but having, according to his custom, rendered solemn thanks to God for his victory, wrote to Prince Potemkin the following Spartan letter: "The Russian colours wave on the ramparts of Ismailow."

Peace being concluded with the Turks in December 1791, no political events occurred from that period to call forth the military talents of Suworow till 1794. In the beginning of that year mutinies having broken out among the Polish troops in the service of Russia, and the Empress, with her two potent allies, having digested the plan for the partition of Poland, Count Suworow received orders, in the month of May, to proceed, by forced marches, into Red Russia, with a corps of 15,000 men, and to disarm all the Polish troops in that province. This service he performed without the effusion of blood, disarming in less than a fortnight 8000 men, dispersed over a country of 150 miles in circuit. Soon afterwards he was ordered to march into the interior of Poland; the King of Prussia having been obliged to raise the siege of Warsaw, and the Empress perceiving that more vigorous measures than had hitherto been pursued, were necessary to accomplish her designs.

To give a detailed account of his route to Warsaw, would be to write the history of the Polish war, and not the memoirs of Count Suworow. It has been rashly supposed, that he had to contend only with raw troops, commanded by inexperienced leaders, who were not cordially united among themselves; but the fact is otherwise, and Suworow never displayed greater resource in the day of danger, than in the numerous battles and skirmishes in which he was engaged on his march to the capital of Poland. At last, after surmounting every obstacle, he sat down, on the 22d of October, before Praga, a strongly fortified suburb of Warsaw, defended by a formidable artillery, and a garrison of 30,000 men, rendered desperate by their situation. The Russian army exceeded not 22,000; and with that comparatively small force he resolved to storm Praga, as he had stormed Ismail. Having erected some batteries to deceive the garrison into a belief that they were to be regularly besieged, he concerted with the other Generals the mode of assault; and when every thing was ready, he gave his orders in these words: "Storm, and take the batteries, and cut down all who resist; but spare the inhabitants, unarmed persons, and all who shall ask for quarter."

There are but few examples of a military operation so boldly conceived, so skilfully performed, or so important in its consequences, as the taking of Praga. The assault was made at once in seven different places at five in the morning; and at nine the Russians were masters of the place, having penetrated by pure force a triple entrenchment. Of the Poles 13,000 lay dead on the field of battle, one third of whom were the flower of the youth of Warsaw; above 2000 were drowned in the Vistula; and 14,080 were taken prisoners, of whom 8000 were disarmed and immediately set at liberty, and the remainder the next day. We mention these circumstances, because they completely refute the tales of those Jacobin scribblers, who have so strenuously endeavoured to tarnish the laurels of the Russian hero, by representing him as having ordered a general massacre of men, women, and children. The artillery taken from the enemy consisted of 104 pieces of cannon and mortars, chiefly of large calibre. The Russians had 580 men killed, of whom eight were superior and staff-officers, and 900 wounded, of whom 23 were officers. Suworow.

Soon after the storming of Praga, Warsaw capitulated, and Suworow was received into the city by the magistrates in a body, and in their ceremonial habits. When the president presented to him the keys of the city, he pressed them to his lips, and then, holding them up towards heaven, he said, "Almighty God, I render thee thanks, that I have not been compelled to purchase the keys of this place as dear as . . . . ." Turning his face towards Praga, his voice failed him, and his cheeks were instantly bathed with tears. As he rode through the streets, the windows were filled with spectators, who were delighted with the return of order, and the assurance of peace; and the air resounded with the exulting exclamations of "Long live Catharine! Long live Suworow!"

Thus did Count Suworow, in the course of a very few months, overturn the kingdom and republic of Poland. It is not our business, in this article, to decide on the justice of the cause in which he was embarked. Of the Polish revolution, which gave rise to the war that subverted the republic, and swept it from the number of sovereign states, the reader will find some account under the title POLAND in the *Encyclopædia*; but it is here proper to acknowledge, that we do not now think so favourably, as when we wrote that article, of the views and principles of those who framed the constitution, which brought upon them the Russian and Prussian arms. Subsequent events seem to have proved completely, that if Poland had not been conquered by the allied powers, it would soon have been involved, under Kosciusko and his Jacobinical adherents, in all the horrors of revolutionary France; and the unhappy king, instead of being carried captive into Russia, would probably have finished his course on a scaffold. Suworow, who never concerned himself with the intrigues of courts, and expressed on all occasions the most sovereign contempt of those Generals who affected to possess the secrets of statesmen, probably never enquired into the final object of the war, but thought it his duty to execute, in his own sphere, the orders of his Imperial mistress. So sensible was Catharine of the propriety of this conduct, and of the zeal and abilities which he had displayed in the Polish campaign, that immediately on receiving accounts of the storming of

Suworow. Praga and the ſubmiſſion of Warſaw, ſhe announced to him, in a letter written with her own hand, his well-earned advancement to the rank of Field-marſhal General. Nor did her munificence ſtop there: She loaded him with jewels, and preſented him with an eſtate of 7000 peaſants, in the diſtrict of Kubin, which had been the ſcene of his firſt battle in the courſe of the campaign.

From the ſubjugation of Poland we hear little more of Field marſhal Suworow till he entered upon his glorious career in Italy. He is ſaid, indeed, to have given offence to the preſent Emperor ſoon after his acceſſion to the throne, by affording protection to ſome meritorious officers, whom his Majeſty had in an arbitrary manner diſmiſſed from the ſervice; but that offence was overlooked, and Suworow called again into action, when Paul joined the coalition againſt France.

Of the exploits of the Field marſhal in Italy, where, to uſe his own words, he deſtroyed armies and overturned ſtates, we have given a full account under the title Revolution in this *Supplement*. In his former campaigns, the wiſdom of his meaſures, the diſtribution of his forces, the undaunted character of his operations, and the progreſſive continuance of his ſucceſs, furniſh proofs of the ſuperiority of his talents hardly to be paralleled in the annals of modern war; but, animated by the nobleneſs of his cauſe, and confiding, as he ſaid, in the God of battles, he ſeems in his laſt campaign to have ſurpaſſed himſelf (B). It would appear, however, that his own Sovereign thought otherwiſe; and if he did, he was certainly as ſingular in that opinion as he is ſaid to be in many others. Conſidering the Field-marſhal as the conqueror of Italy, he had indeed created him a Prince by the ſtyle and title of Prince Suworow-*Italiſki*; but how did he receive him, when he returned into the Ruſſian dominions at the head of his veteran and victorious bands?

Though the old warrior thought himſelf almoſt betrayed at the end of the campaign by the crooked policy of the court of Vienna, he doubtleſs hoped to be received at the court of St Peterſburgh, if not with triumphal arches, at leaſt with the moſt public teſtimo-

(B) Were any other proof than a ſimple narrative of his ſucceſs neceſſary to evince the abilities diſplayed by Marſhal Suworow in the laſt campaign, that proof might be found in the ſad reverſes of the preſent. At the opening of the campaign of 1800, the allies poſſeſſed infinitely greater advantages over the enemy than at the beginning of the campaign of 1799; and we ventured to ſay, towards the end of the article Revolution, in this *Supplement*, that the affairs of the French ſeemed in Italy to be deſperate. But how egregiouſly have we been miſtaken? By the moſt unaccountable infatuation, the Auſtrian commander in Italy would not *believe* that the French army of reſerve, which was advancing upon him with the uſual celerity of the Firſt Conſul's movements, conſiſted of more than *ſix thouſand men!* Inſtead therefore of marching rapidly to meet them before they could be wholly diſentangled from the paſſes over the Alps, he waited patiently for them in the plains of Marengo. If we may judge of the future by the paſt, we may ſurely ſay that ſuch would not have been the conduct of Suworow. Even after the two hoſtile armies met, and fought, on the 10th of July, one of the bloodieſt battles of the preſent war, the ſucceſs of the French was not ſuch as to intitle them to the acquiſitions which were the conſequence of their dear-bought victory. The fate of the day was long doubtful; and it was at laſt decided, not by any extraordinary exertions of the Conſul, but partly by the provident conduct of General Deſſaix, who, with the aid of freſh troops, erected a new battery at a critical point, and at a critical period; and ſtill more by the ſituation of General Melas, whoſe faculties, though frequently ſupported by wine and ſpirits, are ſaid to have wholly forſaken him in the latter part of the day. When he was in this ſtate, one falſe movement, which weakened his centre, afforded an opportunity to Deſſaix to make a vigorous and ſucceſsful charge with a body of cavalry that had not yet been engaged.

But even after this defeat, what was the ſtate of the two armies? The Auſtrians had loſt 6000 men, and the French from 12,000 to 14,000: the former, enraged at having had the victory ſo wreſted out of their hands, were eager to renew the conteſt on the following day; and the latter had obtained only the barren advantage of keeping poſſeſſion of the field of battle. In ſuch a ſituation, Suworow would certainly have encouraged the ardour of his men; but the Auſtrian commander, who complained laſt year of the Field-marſhal for being too little ſparing of blood, inſtead of following the example which he had ſet him at the battle of Trebia, concluded a capitulation unparalleled, we believe, in the annals of war; a capitulation by which he voluntarily ſurrendered into the hands of the enemy nearly all the fruits of one of the moſt glorious campaigns recorded in hiſtory. We wiſh not to throw any undue aſperſion upon the character of General Melas: We believe him to be a brave man, and ſuch he has been repreſented to us in various accounts which we have had directly from Germany; but all theſe accounts agree in repreſenting him likewiſe as fit, not to have the ſupreme command of a great army, but only to execute the orders of a ſuperior mind.

In Germany, the gallant Kray has been obliged to retreat before the equally gallant Moreau; but he has wiſely not hazarded the conſequences of a general action. We ſay *wiſely*; becauſe we have learned from authority which we cannot queſtion, that his army is in a ſtate little better than that of mutiny. To his officers he is in a great meaſure a ſtranger; and therefore theſe gentlemen think themſelves at liberty to diſobey his orders! What the conſequence of all this will be, it becomes not us to conjecture. An armiſtice has in the mean time * taken place both in Italy and in Germany; and it is not impoſſible that the Aulic Council, aided by the mob of Vienna, may induce the Emperor to make a ſeparate peace.—We need hardly make an apology for the length of this note, which our readers will conſider as a continuation, the lateſt that we ſhall have an opportunity to give, of the progreſs of the French revolution, which we once flattered ourſelves would, by this time, have taken a very different turn; and a different turn it would have taken if another Suworow had commanded in Italy.

* September the 4th 1800.

Suworow. nies of his Sovereign's approbation. It is said, that he expected to be sent back at the head of a large army, with full powers to act as he should judge proper for bringing the war to a happy termination, and restoring peace and order to Europe; and he certainly expressed, in letters to different correspondents, his earnest wish to conclude his military career with contributing to the accomplishment of so desirable an object. What then must have been his disappointment, when the Russian Emperor would not see him, and positively forbad his appearance at court? To the messenger who brought the order, the Field-marshal gave a purse of money, turned his carriage another way, and drove to a wooden house, at a distance from the court, and from his former friends, "where burst his mighty heart;" and the conqueror of the Turks, the Poles, and the French republicans, died, almost unattended, on the 18th of May 1800. The sovereign, who thus disgraced him at the end of his life, gave him a magnificent funeral!

In his person Suworow was tall, considerably exceeding six feet, and full chested. His countenance was stern; but among his friends his manners were pleasant, and his dispositions were kind. His temper was naturally violent; but that violence he constantly laboured to moderate, though he was never able completely to extinguish it. According to M. Anthing, an effervescent spirit of impatience predominated in his character; and it perhaps never happened (says that author) that the execution of his orders equalled the rapidity of his wishes. Though he disliked all public entertainments, yet when circumstances led him to any of them, he appeared to partake, and endeavoured to promote, the general pleasure. Sometimes he condescended even to dance and play at cards, though very rarely, and merely that he might not interrupt the etiquette of public manners, to which, when not in the field, he was very attentive. In the field he may be said to have spent the whole of his life from the period at which he first joined the army in the seven years war; for during the time that he was not engaged in actual warfare, and that time, taken altogether, did not exceed twelve years, he was always placed at the head of armies stationed on the frontier of some enemy's country. He was therefore a mere warrior, and as such had no fixed habitation. With respect to his table and lodging, he contented himself with whatever he found, requiring nothing but what absolute necessity demands, and what might be transported with ease from one place to another. His couch consisted of a heap of fresh hay sufficiently elevated, and scattered into considerable breadth, with a white sheet spread over it, with a cushion for his pillow, and with a cloak for his coverlid. He has been represented as dirty (c); but the representation is false. M. Anthing assures, that he was clean in his person, and that, when not on actual service, he washed himself frequently during the course of the day. It is among the singular, though unimportant circumstances of his life (says the same author), that, for the last twenty years, he had not made use of a looking-glass, or incumbered his person with either watch or money.

He was sincerely religious; took every opportunity of attending the offices of public devotion; and has been known, on Sundays and festivals, to deliver lectures on piety to those whom duty called to attend on him. We are told by an anonymous writer, in a miscellany not very forward to praise such men as Suworow, or indeed to praise piety in men of any description, that chancing one evening to overhear a captain abridge the prayer which his duty required him to repeat at the guard, the Field-marshal called out to him, "Thou unconscionable, abominable, impious man, thou wouldst cheat Heaven! Thou wouldst, no doubt, cheat likewise the Empress and me! I shall dismiss thee." His regard for sacred things is indeed very apparent in the elegant letter which, on the 1st of October 1795, he wrote to Charette, the hero of Vendee, whom he congratulates upon taking up arms to restore the temples of the God of his fathers. Alluding to this trait of his character, and to his detestation of Jacobinism under every form, a late writer in a most respectable miscellany has well characterized him as the Suworow.

> "Foe to religion's foe; of Russia's throne
> The prop, th' avenger, and the pride in one;
> Whose conquering arms, in bold defiance hurl'd,
> Crushed the rude monster of the western world."

We have already, when we thought not that we should so soon be called upon to write his life, observed, that he was a scholar, a man of science, and a poet. M. Anthing assures us, that from his earliest years he was enamoured of the sciences, and improved himself in them; but that as the military science was the sole object of his regard, those authors of every nation who investigate, illustrate, or improve it, engrossed his literary leisure. Hence Cornelius Nepos was with him a favourite classic; and he read, with great avidity and attention, the histories of Montecuculi and Turenne. Cæsar, however, and Charles XII. (says the same author) were the heroes whom he most admired, and whose activity and courage became the favourite objects of his imitation.

With respect to his moral character, we have every reason to believe that he was a man of the most incorruptible probity, immoveable in his purposes, and inviolable in his promises; that the cruelties of which he has been accused were the cruelties of Potemkin, and that by those who knew him he was considered as a man of unquestionable humanity. The love of his country, and the ambition to contend in arms for its glory, were the predominant passions of his active life; and to them, like the ancient Romans, he sacrificed every inferior sentiment, and consecrated, without reserve, all the powers of his body and mind. His military career was one long and uniform course of success and triumph, produced by his enterprising courage and extraordinary presence of mind; by his personal intrepidity and promptitude of execution; by the rapid and unparalleled movements of his armies; and by their perfect assurance of victory when fighting under his banners. Such was Alexander Basilovitch Count Suworow. In the year 1774 he married a daughter of the General Prince Iwan Prosorowski, by whom he had two children, now living: Natalia, married to General Count Nicolai Zubow; and Arcadius Count Suworow,

(c) By the anonymous author of the life of Catharine II.

a youth of great promise, who accompanied his father in his unparalleled march from Italy to Switzerland.

SWALLOW's-TAIL, in fortification, is a single tenaille, which is narrower towards the place than toward the country.

SWAN (See ANAS, *Encycl.*). It is now ascertained, beyond the possibility of doubt, that there are *black* swans, of equal size, and the same habitudes, with the common white swan of this island. These fowls have been seen chiefly in New Holland; and Captain Vancouver, when there, saw several of them in very stately attitudes, swimming on the water; and, when flying, discovering the under part of their wings and breasts to be white. Black swans were likewise seen in New Holland by Governor Philips, Captain White, and by a Dutch navigator, so long ago as in 1697. Governor Philips describes the black swan as a very noble bird, larger than the common swan, and equally beautiful in form. Mr White indeed says, that its size is not quite equal to that of the European swan; but both these authors agree with Captain Vancouver in mentioning some white feathers in its wings.

SWINTON (John), a very celebrated English antiquary, was a native of the county of Chester, the son of John Swinton of Bexton in that county, gent. He was born in 1703. The circumstances of his parents were probably not affluent, as he was entered at Oxford in the rank of a servitor at Wadham college. This was in October 1719. It may be presumed, that he recommended himself in that society by his talents and behaviour, as on June 30. 1723, he was elected a scholar on a Cheshire foundation in the college. In the December following, he took his first degree in arts. Before he became master of arts (which was on December 1. 1726), he had chosen the church for his profession, and was ordained deacon by the bishop of Oxford, May 30. 1725; and was afterwards admitted to priest's orders on May 28. 1727. He was not long without some preferment, being admitted to the rectory of St Peter le Bailey in Oxford (a living in the gift of the crown), under a sequestration, and instituted to it in February 1728. In June, the same year, he was elected a fellow of his college; but, desirous probably to take a wider view of the world, he accepted, not long after, the appointment of chaplain to the English factory at Leghorn, to which he had been chosen. In this situation he did not long enjoy his health; and leaving it on that account, he was at Florence in April 1733, where he attended Mr Coleman, the English envoy, in his last moments. Mr Swinton returned thro' Venice and Vienna; and, in company with some English gentlemen of fortune, visited Presburgh in Hungary, and was present at one of their assemblies.

Biog. Dictionary.

It is possible that he had not quitted England in the summer of 1730, for he was elected a Fellow of the Royal Society in June that year, and admitted about three months later. It was probably while he was abroad that he was admitted into some foreign societies; namely, the academy *degli Apatisti* at Florence, and the *Etruscan Academy* of Cortona. On his return, he seems to have taken up his abode at Oxford, where he resided all the latter part of his life, and was for many years chaplain to the gaol in that city. It may be presumed that he married in 1743; it was then, at least, that he gave up his fellowship. In 1759 he became bachelor of divinity: in 1767, he was elected *Custos Archivorum*, or keeper of the university records: and, on April 1. 1777, he died; leaving no children. His wife survived till 1784, and both were buried, with a very short and plain inscription, in the chapel of Wadham college.

It remains to take notice of the most important monuments of a literary man's life, his publications. These were numerous and learned, but not of great magnitude. He published, 1. "De Linguæ Etruriæ Regalis vernacula Dissertatio," 4to, 19 pages, Oxon, 1738. 2. "A critical essay concerning the words Δαίμων and Δαιμόνιον, occasioned by two late inquiries into the meaning of the demoniacs in the New Testament," 8vo, London, 1739. 3. "De priscis Romanorum literis dissertatio," 4to, 20 pages, Oxon. 1746. 4 "De Primogenio Etruscorum Alphabeto, dissertatio," Oxon, 1746. 5. "Inscriptiones Citieæ: sive in binas Inscriptiones Phœnicias, inter rudera Citii nuper repertas, conjecturæ. Accedit de nummis quibusdam Samaritanis et Phœnicius, vel insolitam præ se literaturam ferentibus, vel in lucem hactenus non editis, dissertatio," 4to, 87 pages, Oxon, 1750. 6 "Inscriptiones Citieæ: sive in binas alias Inscriptiones Phœnicias, inter rudera Citii nuper repertas, conjecturæ," 4to, 19 pages. 7. "De nummis quibusdam Samaritanis et Phœniciis, vel insolitam præ se literaturam ferentibus, vel in lucem hactenus non editis. dissertatio secunda," 4to, 36 pages 8. "Metilia: sive de quinario Gentis Metiliæ, e nummis vetustis cæteroquin minimum notæ, dissertatio," 4to, 22 pages. Oxon, 1750. 9. Several dissertations published in the Philosophical Transactions of the Royal Society. As, "A dissertation upon a Parthian Coin; with characters on the reverse resembling those of the Palmyrenes," vol. xlix. p. 593. "Some remarks on a Parthian Coin, with a Greek and Parthian legend, never before published," vol. l. p. 16. "A dissertation upon the Phœnician numeral characters anciently used at Sidon," vol. l. p. 791. "In nummum Parthicum hactenus ineditum conjectura," vol. li. p. 683. "A dissertation upon a Samnite Denarius, never before published," vol. lii. p. 28. "An account of a subærated Denarius of the Plætorian family, adorned with an Etruscan inscription on the reverse, never before published or explained," vol. lxii. p. 60. "Observations upon five ancient Persian Coins, struck in Palestine or Phœnicia before the dissolution of the Persian empire," vol. lxii. p. 345. Other papers by him may be found in the general index to the Philosophical Transactions. 10. A part of the Ancient Universal History, contained in the sixth and seventh volumes of that great work. The particulars of this piece of literary history were communicated by Dr Johnson to Mr Nichols, in a paper printed in the Gentleman's Magazine for December 1784, p. 892. The original of that paper, which affords a strong proof of the steady attachment of Johnson to the interests of literature, has been, according to his desire, deposited in the British Museum. The letter is as follows:

"To Mr Nichols.

"The late learned Mr Swinton of Oxford having one day remarked, that one man, meaning, I suppose, no man but himself, could assign all the parts of the Universal History to their proper authors, at the request of Sir Robert Chambers, or of myself, gave the account which I now transmit to you in his own hand,

being willing, that of so great a work the history should be known, and that each writer should receive his due proportion of praise from posterity. I recommend to you to preserve this scrap of literary intelligence, in Mr Swinton's own hand, or to deposite it in the Museum, that the veracity of the account may never be doubted.—I am, Sir, your most humble servant,

Dec. 6, 1784 SAM. JOHNSON."

The paper alluded to, besides specifying some parts written by other persons, assigns the following divisions of the history to Mr Swinton himself "The history of the Carthaginians, Numidians, Mauritanians, Gætulians, Garamantes, Melano Gætulians, Nigritæ, Cyrenaica, Marmarica, the Regio Syrtica, Turks, Tartars, and Moguls, Indians, and Chinese, a dissertation on the peopling of America, and one on the independency of the Arabs.

Swinton.

In the year 1740, Mr Swinton was involved in a law suit, in consequence of a letter he had published. It appears from a paper of the time *, that a letter from the Rev. Mr Swinton, highly reflecting on Mr George Baker, having fallen into the hands of the latter, the court of King's Bench made the rule absolute for an information against Mr Swinton. These two gentlemen were also engaged for some time in a controversy at Oxford; which took its rise from a matter relative to Dr Thistlethwaite, some time warden of Wadham, which then attracted much attention. Mr Swinton had the manners, and some of the peculiarities, often seen in very recluse scholars, which gave rise to many whimsical stories Among the rest, there is one mentioned by Mr Boswell, in the Life of Johnson, as having happened in the year 1754. Johnson was then on a visit in the university of Oxford. "About this time (he says) there had been an execution of two or three criminals at Oxford, on a Monday. Soon afterwards, one day at dinner, I was saying that Mr Swinton, the chaplain of the gaol, and also a frequent preacher before the university, a learned man, but often thoughtless and absent, preached the condemnation sermon on repentance, before the convicts, on the preceding day, Sunday; and that, in the close, he told his audience, that he should give them the remainder of what he had to say on the subject the next Lord's day. Upon which, one of our company, a doctor of divinity, and a plain matter-of-fact man, by way of offering an apology for Mr Swinton, gravely remarked, that he had probably preached the same sermon before the university. Yes, Sir (says Johnson); but the university were not to be hanged the next morning!"

* *The Champion, or Evening Advertiser*, June 17th 174-.

T.

Tacquet ‖ Talus.

TACQUET (Andrew), a Jesuit of Antwerp, who died in 1660. He was a most laborious and voluminous writer in mathematics. His works were collected, and printed at Antwerp, in one large volume in folio, 1669.

TALLOW-TREE. See CROTON (*Encycl.*), where, however, we have fallen into a mistake, which it is here our duty to correct. We learn from Sir George Staunton, that the candles made of the vegetable tallow are firmer than those made of animal tallow, and free from all offensive smell, contrary to what was rashly said in the article referred to. They are not, however, equal to those of wax or spermaceti; but the latter of these substances is not within the reach of the Chinese, and the art of blanching the former is little known to them. The tallow tree is said to have been transplanted to Carolina, and to flourish there as well as in China

TALOOK, an Arabic word, which signifies literally attachment, connection, dependence. In Bengal, however, where it occurs perpetually in the enumeration of the districts and subdivisions of that province contained in the institutes of Akber, it signifies a tenure of land. Hence the *talook* of Cathinat, the *talook* of Meheys the headman, the *talook* of Ahmed Khan, &c. See *A Dissertation concerning the Landed Property of Bengal*, by Sir Charles Rouse Boughton.

TALOOKDAR, the possessor of a talook.

TALOOKDARY, tenure of a talookdar.

TALUS, or TALUD, in architecture, the inclination or slope of a work; as of the outside of a wall, when its thickness is diminished by degrees, as it rises in height, to make it the firmer.

Talus ‖ Tanning.

TALUS, in fortification, means also the slope of a work, whether of earth or masonry.

TAMASCAL, the name given in California to a kind of sand-bath employed by the natives in the cure of the venereal disease. It is prepared by scooping a trench in the sand, two feet wide, one foot deep, and of a length proportioned to the size of the patient; a fire is then made through the whole extent of it, as well as upon the sand which was dug out of the hollow. When the whole is thoroughly heated, the fire is removed, and the sand stirred about, that the warmth may be equally diffused. The sick person is then stripped, laid down in the trench, and covered up to his chin with heated sand. In this position a very profuse sweat soon breaks out, which gradually diminishes according as the sand cools. The patient then rises and bathes in the sea, or the nearest river This process is repeated till a complete cure is obtained. While the patient is undergoing the operation of the tamascal, he drinks a considerable quantity of a warm sudorific, prepared by the decoction of certain herbs, chiefly of the shrub called by the Spaniards GOUVERNANTE, which see in this *Supplement*.

TAN is a substance found in most vegetables, which, not having hitherto been resolved into component parts, is therefore considered as simple. See *Vegetable and Animal Substances* in this *Suppl.*

TANNING is an art, of which a full account, according to the general practice in London and its vicinity, has been given under the proper title in the *Encyclopædia*. But since that article was written, the superior knowledge which has been obtained of the tan-

ning principle, as well as of the composition of the skins of animals (See *Vegetable and Animal Substances, Suppl.*), has suggested to scientific artists various methods of shortening the process by which leather is manufactured. Mr Seguin is said to have thrown much light upon the art of the tanner as it is practised in France; and in 1795 Mr William Desmond obtained a patent for practising Seguin's method in England. He obtains the tanning principle by digesting oak bark, or other proper material, in cold water, in an apparatus nearly similar to that used in the saltpetre works. That is to say, the water which has remained upon the powdered bark for a certain time, in one vessel, is drawn off by a cock, and poured upon fresh tan. This is again to be drawn off, and poured upon other fresh tan; and in this way the process is to be continued to the fifth vessel. The liquor is then highly coloured, and marks, as Mr Desmond says, from six to eight degrees on the hydrometer for salts. He calls this the tanning lixivium. The criterion to distinguish its presence is, that it precipitates glue from its aqueous solution, and is also useful to examine how far other vegetable substances, as well as oak bark, may be suitable to the purpose of tanning. The strong tanning liquor is to be kept by itself. It is found by trials with the glue, that the tanning principle of the first digester which receives the clear water, is, of course, first exhausted. But the same tan will still give a certain portion of the astringent principle, or gallic lixivium, to water. The presence of this principle is ascertained by its striking a black colour when added to a small quantity of the solution of vitriol of iron or green copperas. As soon as the water from the digester ceases to exhibit this sign, the tan is exhausted, and must be replaced with new. The gallic lixivium is reserved for the purpose of taking the hair off from hides.

Strong hides, after washing, cleaning, and fleshing, in the usual way, are to be immersed for two or three days in a mixture of gallic lixivium and one thousandth part by measure of dense vitriolic acid. By this means the hair is detached from the hides, so that it may be scraped off with a round knife. When swelling or raising is required, the hides are to be immersed for ten or twelve hours in another vat filled with water and one five-hundredth part of the same vitriolic acid. The hides being then repeatedly washed and dressed, are ready for tanning; for which purpose they are to be immersed for some hours in a weak tanning lixivium of only one or two degrees; to obtain which, the latter portions of the infusions are set apart; or else some of that which has been partly exhausted by use in tanning. The hides are then to be put into a stronger lixivium, where in a few days they will be brought to the same degree of saturation with the liquor in which they are immersed. The strength of the liquor will by this means be considerably diminished, and must therefore be renewed. When the hides are by this means completely saturated, that is to say, perfectly tanned, they are to be removed, and slowly dried in the shade.

Calf skins, goat skins, and the like, are to be steeped in lime-water after the usual fleshing and washing. These are to remain in the lime water, which contains more lime than it can dissolve, and requires to be stirred several times a day. After two or three days, the skins are to be removed, and perfectly cleared of their lime by washing and pressing in water. The tanning process is then to be accomplished in the same manner as for the strong hides, but the lixivium must be considerably weaker. Mr Desmond remarks, that lime is used instead of the gallic lixivium for such hides as are required to have a close grain; because the acid mixed with that lixivium always swells the skins more or less; but that it cannot with the same convenience be used with thick skins, on account of the considerable labour required to clear them of the lime; any part of which, if left, would render them harsh and liable to crack. He recommends, likewise, as the best method to bring the whole surface of the hides in contact with the lixivium, that they should be suspended vertically in the fluid by means of transverse rods or bars, at such a distance as not to touch each other. By this practice much of the labour of turning and handling may be saved.

Mr Desmond concludes his specification, by observing, that in some cases it will be expedient to mix fresh tan with the lixivium; and that various modifications of strength, and other circumstances, will present themselves to the operator. He affirms that, in addition to the great saving of time and labour in this method, the leather, being more completely tanned, will weigh heavier, wear better, and be less susceptible of moisture than leather tanned in the usual way; that cords, ropes, and cables, made of hemp or speartery, impregnated with the tanning principle, will support much greater weights without breaking, be less liable to be worn out by friction, and will run more smoothly on pulleys; insomuch that, in his opinion, it will render the use of tar in may cases, particularly in the rigging of ships, unnecessary; and, lastly, that it may be substituted for the preservation of animal food instead of salt.

Mr Nicholson, from whose Philosophical Journal we have taken this account of Mr Desmond's method of tanning, made some very proper enquiries at one of the first manufacturing houses in the borough of Southwark, concerning its value. He was told by one of the partners, that the principle upon which the new process is founded had been long known to them; but that they preferred the old and slower method, because the hides are found to feed and improve in their quality by remaining in the pit. He could gain no satisfactory information of what is meant by this feeding and improving; and; without taking upon us to decide between the advantages peculiar to Desmond's method and those of the common practice, we cannot help saying that this objection of the tanner at Southwark appears to us to be that of a man who either understands not the principles of his own art, or has some reason for opposing the progress of improvement, if it do not originate in his own house.

TASSIE (James) modeller, whose history is intimately connected with a branch of the fine arts in Britain, was born in the neighbourhood of Glasgow of obscure parents; and began his life as a country stone mason, without the expectation of ever rising higher. Going to Glasgow on a fair day, to enjoy himself with his companions, at the time when the Foulis's were attempting to establish an academy for the fine arts in that city, he saw their collection of paintings and felt an irresistible impulse to become a painter. He removed to Glasgow; and in the academy acquired a knowledge of drawing, which unfolded and

improved his natural taste He was frugal, industrious, and persevering; but he was poor, and was under the necessity of devoting himself to stone-cutting for his support: not without the hopes that he might one day be a statuary if he could not be a painter. Resorting to Dublin for employment, he became known to Dr Quin, who was amusing himself in his leisure hours with endeavouring to imitate the precious stones in coloured pastes, and take accurate impressions of the engravings that were on them.

That art was known to the ancients; and many specimens from them are now in the cabinets of the curious. It seems to have been lost in the middle ages; was revived in Italy under Leo X. and the Medici family at Florence; became more perfect in France under the regency of the Duke of Orleans, by his labours and those of Homberg. By those whom they instructed as assistants in the laboratory it continued to be practised in Paris, and was carried to Rome. Their art was kept a secret, and their collections were small. It is owing to Quin and to Tassie that it has been carried to such high perfection in Britain, and attracted the attention of Europe.

Dr Quin, in looking out for an assistant, soon discovered Tassie to be one in whom he could place perfect confidence. He was endowed with fine taste: he was modest and unassuming: he was patient; and possessed the highest integrity. The Doctor committed his laboratory and experiments to his care. The associates were fully successful; and found themselves able to imitate all the gems, and take accurate impressions of the engravings.

As the Doctor had followed the subject only for his amusement, when the discovery was completed, he encouraged Mr Tassie to repair to London, and to devote himself to the preparation and sale of those pastes as his profession.

In 1766 he arrived in the Capital. But he was diffident and modest to excess; very unfit to introduce himself to the attention of persons of rank and of affluence: besides, the number of engraved gems in Britain was small; and those few were little noticed. He long struggled under difficulties which would have discouraged any one who was not possessed of the greatest patience, and the warmest attachment to the subject. He gradually emerged from obscurity, obtained competence; and what to him was much more, he was able to increase his collection, and add higher degrees of perfection to his art. His name soon became respected, and the first cabinets in Europe were open for his use; and he uniformly preserved the greatest attention to the exactness of the imitation and accuracy of the engraving, so that many of his pastes were sold on the Continent by the fraudulent for real gems. His fine taste led him to be peculiarly careful of the impression; and he uniformly destroyed those with which he was in the least dissatisfied. The art has been practised of late by others; and many thousands of pastes have been sold as Tassie's, which he would have considered as injurious to his fame. Of the fame of others he was not envious; for he uniformly spake with frankness in praise of those who executed them well, though they were endeavouring to rival himself.

To the ancient engravings he added a numerous collection of the most eminent modern ones; many of which approach in excellence of workmanship, if not in simplicity of design and chastity of expression, to the most celebrated of the ancient. Many years before he died he executed a commission for the late Empress of Russia, consisting of about 15,000 different engravings (See GEM, *Encycl.*). At his death, in 1799, they amounted to near 20,000; a collection of engravings unequalled in the world. Every lover of the fine arts must be sensible of the advantage of it for improvement in knowledge and in taste. The collection of Feloix at Paris consisted of 1800 articles; and that of Dehn at Rome of 2500.

For a number of years, Mr Tassie practised the modelling of portraits in wax, which he afterwards moulded and cast in paste. By this, the exact likeness of many eminent men of the present age will be transmitted to posterity as accurately as those of the philosophers and great men have been by the ancient statuaries. In taking likenesses he was, in general, uncommonly happy; and it is remarkable, that he believed there was a certain kind of inspiration (like that mentioned by the poets) necessary to give him full success. The writer of this article, in conversing with him repeatedly on the subject, always found him fully persuaded of it. He mentioned many instances in which he had been directed by it; and even some, in which, after he had laboured in vain to realize his ideas on the wax, he had been able, by a sudden flash of imagination, to please himself in the likeness several days after he had last seen the original.

He possessed also an uncommonly fine taste in architecture, and would have been eminent in that branch if he had followed it.

In private life Mr Tassie was universally esteemed for his uniform piety, and for the simplicity, the modesty, and benevolence, that shone in the whole of his character.

TASTELESS EARTH (*agust erde*), the name given by Professor Trommsdorff to a new simple earth, which he discovered in the Saxon beryl. It is distinguished (he says) from other earths by the following properties: It is white, and totally insoluble in water. In a fresh state, when moistened with water, it is somewhat ductile. In the fire it becomes transparent and very hard, so as to scratch glass, but remains insipid and insoluble in water. The burnt earth dissolves very easily in acids, and produces with them peculiar salts, which are entirely devoid of taste; and hence he gave it the name of *tasteless earth*. Fixed alkalies do not dissolve this earth either in the dry or in the wet way; and it is equally insoluble with the carbonic acid and with caustic ammonia. It has a greater affinity to the oxalic than to other acids. Professor Trommsdorff informs us, that a full account of this earth, accompanied with an accurate description, by Dr Bernhardi, of the fossil in which it is found, will appear in the first part of the eight volume of his *Journal of Pharmacy*.

TEETH, of various sorts of machines, as of mill wheels, &c. These are often called cogs by the workmen; and by working in the pinions, rounds, or trundles, the wheels are made to turn one another. Mr Emerson (in his Mechanics, prop. 25.) treats of the theory of teeth, and shews that they ought to have the figure of epicycloids, for properly working in one another.

TEKAWY, in Bengal, money advanced by government

Telescope, Temperament of the Scale of Music.

ment to the proprietors or cultivators of land to aſſiſt them under circumſtances of diſtreſs.

TELESCOPE, is an inſtrument which has been ſo completely deſcribed in the *Encyclopædia*, that it is introduced into this place merely to notice an ingenious ſuggeſtion of Mr Nicholſon's for improving the achromatic teleſcope, by adding an artificial iris to the object glaſs. Suppoſe (ſays he) a braſs ring to ſurround the object end of the teleſcope, and upon this let eight or more triangular ſlips of braſs be fixed, ſo as to revolve on equi-diſtant pins paſſing through each triangle near one of its corners. If the triangles be ſlided inwards upon each other, it may readily be apprehended that they will cloſe the aperture; and if they be all made to revolve or ſlide backwards alike, it is clear that their edges will leave an octagonal aperture, greater or leſs according to circumſtances. The equable motion of all the triangles may be produced either by pinions and one concave toothed wheel, or by what is called ſnail-work. Another kind of iris, more compact, may be made, by cauſing thin elaſtic ſlips of braſs to ſlide along parallel to the tube, and be conducted each through a ſlit in a braſs cap which ſhall lead them acroſs the aperture in a radial direction. It is probable alſo that the artiſt, who ſhall carry theſe hints into effect, may alſo think of ſeveral other methods.

This thought occurred to the author, from contemplating the contraction and dilatation of the iris of the eye, according as we look at an object more or leſs luminous. Theſe variations are ſo great, that in the obſervable variations of the human eye, the aperture is thirty times as large at one time as at another, whilſt in the cat the proportion is greater than a hundred to one.

TEMPERAMENT OF THE SCALE OF MUSIC.

1 Introduction.

When the conſiderate reader reflects on the large and almoſt numberleſs diſſertations on this ſubject, by the moſt eminent philoſophers, mathematicians, and artiſts, both of ancient and modern times, and the important points which divided, and ſtill divide, their opinions, he will not ſurely expect, in a Work like our's, the deciſion of a queſtion which has hitherto eluded their reſearches. He will rather be diſpoſed, perhaps, to wonder how a ſubject of this nature ever acquired ſuch importance in the minds of perſons of acknowledged talents (for ſurely no perſon will refuſe this claim to Pythagoras, to Ariſtotle, Euclid, Ptolemy, Galileo, Wallis, Euler, and many others, who have written elaborate treatiſes on the ſubject); and his ſurpriſe will increaſe, when he knows that the treatiſes on the ſcale of muſic are as numerous and voluminous in China, without any appearance of their being borrowed from the ingenious and ſpeculative Greeks.

The ingenious, in all cultivated nations, have remarked the great influence of muſic; and they found no difficulty in perſuading the nations that it was a gift of the gods. Apollo and his ſacred choir are perhaps the moſt reſpectable inhabitants of the mythological heavens of the Greeks. Therefore all nations have conſidered muſic as a proper part of their religious worſhip. We doubt not but that they found it fit for exciting or ſupporting thoſe emotions and ſentiments which were ſuited to adoration, thanks, or petition. Nor would the Greeks have admitted muſic into their ſerious dramas, if they had not perceived that it heightened the effect. The ſame experience made them employ it as an aid to military enthuſiaſm; and it is recorded as one of the reſpectable accompliſhments of Epaminondas, that he had the muſical inſtructions of the firſt maſters, and was eminent as a performer.

Thus was the ſtudy of muſic ennobled, and recommended to the attention of the greateſt philoſophers. Its cultivation was held an object of national concern, and its profeſſors were not allowed to corrupt it in order to gratify the faſtidious taſte of the luxurious or the ſenſualiſt, who ſought from it nothing but amuſement. But its influence was not confined to theſe public purpoſes; and, while the men of ſpeculation found in muſic an inexhauſtible fund of employment for their genius and penetration, and their poets felt its aid in their compoſitions, it was hailed by perſons of all ranks as the ſoother of the cares and anxieties, and ſweetener of the labours of life. *O Phœbi decus!—laborum dulce lenimen.* Poor Ovid, the victim of what remained of good in the cold heart of Octavius, found its balm.

Exul eram (ſays he): *requieſque mihi, non fama petita eſt*
Mens intenta ſuis ne foret uſque malis.
Hoc eſt cur cantet vinctus quoque compede foſſor,
Indocili numero cum grave molit opus.
Cantet et innitens limoſæ pronus arenæ
Adverſo tardam qui trahit amne ratem,
Quique ferens pariter lentos ad pectora remos,
In numerum pulsâ brachia verſat aquâ.
Feſſus ut incubuit baculo, ſaxove reſedit
Paſtor; arundineo carmine mulcet oves.
Cantantis pariter, pariter data penſa trahentis
Fallitur ancillæ, decipiturque labor.

2 Scale of muſic. It requires temperament.

It is chiefly in this humble department of muſical influence that we propoſe at preſent to lend our aid. What has been ſaid in the article Music, *Encycl.* is ſufficient for informing the reader of what is received as the ſcale of muſic, and the inequality of its different ſteps, the tones major and minor, ſemitone, comma, &c. We ſhall only obſerve, that what is there delivered on temperament by M. d'Alembert, after Rameau, bears the evident mark of uncertainty or want of confidence in the principle adopted as the rule of temperament; and we have learned, ſince the printing of that article, that the inſtructions there delivered have not that perſpicuity and preciſion that are neceſſary for enabling a perſon to execute the temperament recommended by Rameau; that is, to tune a keyed inſtrument with certainty, according to that ſyſtem or conſtruction of the ſcale.

If ſuch be the caſe, we are in ſome meaſure diſappointed; becauſe we ſelected that treatiſe of D'Alembert as the performance of a man of great eminence as a mathematician and philoſopher, aiming at public inſtruction more than his own fame, by this elementary abſtract of the great work of the moſt eminent muſician in France.

Few can tune a harpſichord;

To be able to tune a harpſichord with certainty and accuracy, ſeems an indiſpenſable qualification of any perſon worthy of the name of a *muſician*. It would certainly be thought an unpardonable deficiency in a violin performer if he could not tune his inſtrument; yet we are well informed, that many profeſſional performers on the harpſichord cannot do it, or cannot do it any other way than by uncertain and painful trial, and, as it were, groping

Temperament of the Scale of Music.

groping in the dark; and that the tuning of harpsichords and organs is committed entirely to tuners by profession. This is a great inconvenience to persons residing in the country; and therefore many take lessons from the professed harpsichord tuners, who also profess to teach this art. We have been present during some of these lessons; but it did not appear to us that the instructions were such as could enable the scholar to tune an instrument when alone, unless the lessons had been so frequent as to form the ear to an instantaneous judgment of tune by the same habit that had instructed the teacher. There seemed to be little principle that could be treasured up and recollected when wanted.

3 Yet Nature furnishes abundant means of doing this.

Yet we cannot help thinking that there are phenomena or facts in music, sufficiently precise to furnish principles of absolute certainty for enabling us to produce temperaments of the scale which shall have determined characters, and among which we may choose such a one as shall be preferable to the others, according to the purposes we have in view; and we think that these principles are of such easy application, that any person, of a moderate sensibility to just intonation, may, without much knowledge or practice in music, tune his harpsichord with all desirable accuracy. We propose to lay these before the reader. We might content ourselves with simply giving the practical rules deduced from the principles; but it is surely more desirable to perceive the validity of the principles. This will give us confidence in the deduced rules of practice. In the employment of sacred music, an inspired writer counsels us to sing, not only "with the heart, but with the understanding also." We may, without irreverence, recommend the same thing here. Let us therefore attend a little to the dictate of untutored Nature, and see how she teaches all mankind to form the scale of melody.

All nations sing by one scale.

It is a most remarkable fact, that, in all nations, however they may differ in the structure of that chaunt which we call the accent, or tone, or twang, in the colloquial language of a particular nation, or in the favourite phrases or passages which are most frequent in their songs, all men make use of the same rises and falls, or inflexions of voice, in their musical language or airs. We have heard the songs of the Iroquois, the Cherokee, and the Esquimaux, of the Carib, and the inhabitant of Paraguay; of the African of Negroland and of the Cape, and of the Hindoo, the Malay, and the native of Otaheite—and we found none that made use of a different scale from our own, although several seemed to be very sorry performers by any scale. There must be some natural foundation for this uniformity. We may never discover this; but we may be fortunate enough to discover facts in the phenomena of sound which invariably accompany certain modifications of musical sentiment. If we succeed, we are intitled to suppose that such inseparable companions are naturally connected; and to conclude, that if we can insure the appearance of those facts in sound, we shall also give occasion to those musical sentiments or impressions.

5 Musical pitch, what?

There is a quality in lengthened or continued sound which we call its pitch or note, by which it may be accounted shrill or hoarse. It may be very hoarse in the beginning, and during its continuance it may grow more and more shrill by imperceptible gradations. In this case we are sensible of a kind of progress from the one state of sound to the other. Thus, while we gently draw the bow across the string of a bass viol, if we at the same time slide the finger slowly along the string, from the nut toward the bridge, the sound, from being hoarse, becomes gradually acute or shrill. Hoarse and shrill therefore are not different qualities, although they have different names, but are different states or degrees of the same quality, like cold and heat, near and far, early and late, or, what is common to all these, little and great. A certain state of the air is accounted neither hot nor cold. All states on one side of this are called warm, or hot; and all on the other are cold. In like manner, a certain sound is the boundary between those that are called hoarse and those called shrill. The chemist is accustomed to say, that the temperature of a body is higher when it is warmer, and lower when colder. In like manner, we are accustomed to say, that a person raises or depresses the pitch of his voice when it becomes more shrill or more hoarse. The ancient Greeks, however, called the shriller sounds *low*, and the hoarser sounds *high*; probably because the hoarser sounds are generally stronger or louder, which we are also accustomed to consider as higher. In common language, a low pitch of voice means a faint sound, but in musical language it means a hoarser sound. The sound that is neither hoarse nor shrill is some ordinary pitch of voice, but without any precise criterion.

The change observed in the pitch of a violin string, when the finger is carried along the finger-board with a continued motion, is also continuous; that is, not by starts: we call it gradual, for want of a better term, although gradual properly means *gradatim*, by degrees, steps, or starts, which are not to be distinguished in this experiment. But we may make the experiment in another way. After sounding the open string, and while the bow is yet moving across it, we may put down the finger about $1\frac{2}{3}$ inches from the nut. This will change the sound into one which is *sensibly* shriller than the former, and there is a manifest start from the one to the other. Or we may put down the finger $2\frac{1}{2}$ inches from the nut; the sound of the open string will change to a shriller sound, and we are sensible that this change or step is greater than the former. Moreover, we may, while drawing the bow across the string, put down one finger at $1\frac{2}{3}$ inches, and, immediately after, put down another finger at $2\frac{1}{2}$ inches from the nut. We shall have three sounds in succession, each more shrill than the preceding, with two manifest steps, or subsultory changes of pitch.

Now since the last sound is the same as if the second had not been sounded, we must conceive the sum of the two successive changes as equivalent, or equal to the change from the first to the third. This change seems somehow to include the other two, and to be made up of them, as a whole is made up of its parts, or as $2\frac{1}{2}$ inches are made up of $1\frac{2}{3}$ and $\frac{5}{6}$ of an inch, or as the sum 15 is made up of 10 and 5.

8 We have a notion of something like an interval between the notes of music.

Thus it happens that thinking persons conceive something like or analogous to a distance, or interval, between these sounds. It is plain, however, that there can be no real distance or space interposed between them; and it is not easy to acquire a distinct notion of the bulk or magnitude of these intervals. This conception is purely figurative and analogical; but the analogy is very good, and the observation of it, or conjecture

Temperament of the Scale of Music.

jecture about it, has been of great ſervice in the ſcience of muſic, by making us ſearch for ſome preciſe meaſure of thoſe manifeſt intervals of muſical ſounds.

9. It muſt now be remarked, that it is in this reſpect alone that ſounds are ſuſceptible of muſic. Nor are all ſounds poſſeſſed of this quality. The ſmack of a whip, the exploſion of a muſket, the ruſhing of water or wind, the ſcream of ſome animals, and many other ſounds, both momentary and continuous, are mere noiſes; and can neither be called hoarſe nor ſhrill. But, on the other hand, many ſounds, which differ in a thouſand circumſtances of loudneſs, ſmoothneſs, mellowneſs, &c. which make them pleaſant or diſagreeable, have this quality of muſical pitch, and may thus be compared. The voice of a man or woman, the ſound of a pipe, a bell, a ſtring, the voice of an animal, nay, the ſingle blow on an empty caſk—may all have one pitch, or we may be ſenſible of the interval between them. We can, in all caſes, tighten or ſlacken the ſtring of a violin, till the moſt uninformed hearer can pronounce with certainty that the pitch is the ſame. We are indebted to the celebrated Galileo for the diſcovery of that phyſical circumſtance in all thoſe ſounds which communicates this remarkable quality to them, and even enables us to induce it on any noiſe whatever, and to determine, with the utmoſt preciſion, the muſical pitch of the ſound, and the interval between any two ſuch ſounds. Of this we ſhall ſpeak fully hereafter; and at preſent we only obſerve, that two ſounds, having the ſame pitch, are called UNISONS by muſicians, or are ſaid to be in *uniſon* to one another.

When two untaught men attempt to ſing the ſame air together, they always ſing in uniſon, unleſs they expreſsly mean to ſing in different pitches of voice. Nay, it is an extremely difficult thing to do otherwiſe, except in a few very peculiar caſes. Alſo, when a man and woman, wholly uninſtructed in muſic, attempt to ſing the ſame air, they alſo *mean* to ſing the ſame muſical notes through the whole air; and they generally imagine that they do ſo. But there is a manifeſt difference in the ſounds which they utter, and the woman is ſaid to ſing more SHRILL, and the man more HOARSE. A very plain experiment, however, will convince them that they are miſtaken. *N. B.* We are now ſuppoſing that the performers have ſo much of a muſical ear, and flexible voice, as to be able to ſing a common ballad, or a pſalm tune, with tolerable exactneſs, and that they can prolong or dwell upon any particular note when deſired.

Let them ſing the common pſalm tune called St David's, in the ſame way that they practiſe at church; and when they have done it two or three times, in order to fix their voices in tune, and to feel the general impreſſion of the tune, let the woman hold on in the firſt note of the tune, which we ſuppoſe to be *g*, while the man ſings the firſt three in ſucceſſion, namely *g*, *d*, *g*. He will now perceive, that the laſt note ſung by himſelf is the ſame with that ſung by the woman, and which ſhe thinks that ſhe is ſtill holding on in the firſt note of the tune. Let this be repeated till the performance becomes eaſy. They will then perceive the perfect ſameneſs, in reſpect of muſical pitch, of the woman's firſt note of this tune and the man's third note. Some difference, however, will ſtill be perceived; but it will not be in the pitch, but in the ſmoothneſs, or clearneſs, or other agreeable quality of the woman's note.

Temperament of the Scale of Music.

When this is plainly perceived, let the man try by what continued ſteps he muſt raiſe his pitch, in order to arrive at the woman's note from his own. If he is accuſtomed to common ballad ſinging, he will have no great difficulty in doing this; and will find that, beginning with his own note, and ſinging gradually up, his eighth note will be the woman's note. In ſhort, if two flutes be taken, one of which is twice as long as the other, and if the man ſing in uniſon with the large flute, the woman, while ſinging, as ſhe thinks, the ſame notes with the man, will be found to be ſinging in uniſon with the ſmaller flute.

In ſteps of a ſcale, eight notes.

This is a remarkable and moſt important fact in the phenomena of muſic. This interval, comprehending and made up of ſeven ſmaller intervals, and requiring eight ſounds to mark its ſteps, is therefore called an OCTAVE. Now, ſince the female performer follows the ſame dictates of natural ear in ſinging her tune that the man follows in ſinging his, and all hearers are ſenſible that they are ſinging the ſame tune, it neceſſarily follows, that the two ſerieſes of notes are perfectly ſimilar, though not the ſame: For there muſt be the ſame interval of an octave between any ſtep of the lower octave and the ſame ſtep of the upper one. In whatever way, therefore, we conceive one of theſe octaves to be parcelled out by the different ſteps, the partition of both muſt be ſimilar. If we repreſent both by lines, theſe lines muſt be ſimilarly divided. Each partial interval of the one muſt bear the ſame relation to the whole, or to any other interval, as its ſimilar interval in the other octave bears to the whole of that octave, or to the other correſponding interval in it.

11 Octave.

12 All octaves are ſimilar.

Farther, we muſt now obſerve, that although this ſimilarity of the octaves was firſt obſerved or diſcovered by means of the ordinary voices of man and woman, and is a legitimate inference from the perfect ſatisfaction that each feels in ſinging what they think the ſame notes, this is not the only foundation or proof of the ſimilarity. Having acquired the knowledge of that phyſical circumſtance, on which the pitch of muſical ſounds depends, we can demonſtrate, with all the rigour of geometry, that the ſeveral notes in the man and woman's octave *muſt* have the ſame relation to their reſpective commencements, and that theſe two great intervals are ſimilarly divided. But farther ſtill, we can demonſtrate that this ſimilarity is not confined to theſe two octaves. This may even be proved, to a certain extent, by the ſame original experiment. Many men can ſing two octaves in ſucceſſion, and there are ſome rare examples of perſons who can ſing three. This is more common in the female voice. This being the caſe, it is plain that there will be two octaves common to both voices; and therefore four octaves in ſucceſſion, all ſimilar to each other. The ſame ſimilarity may be obſerved in the ſounds of inſtruments which differ only by an octave. And thus we demonſtrate that all octaves are ſimilar to each other. This ſimilarity does not conſiſt merely in the ſimilarity of its diviſion. The ſound of a note and its octave are ſo like each other, that if the ſtrength or loudneſs be properly adjuſted, and there be no difference in kind, or other circumſtances of clearneſs, ſmoothneſs, &c. the two notes, when ſounded together, are indiſtinguiſhable, and appear only like a more brilliant note. They coaleſce into one ſound. Nay, moſt clear mellow notes, ſuch as thoſe of a fine human

 voice,

Temperament of the Scale of Muſic

voice, really contain each two notes, one of which is octave to the other.

We ſaid that this reſemblance of octaves is an important fact in the ſcience of muſic. We now ſee why it is ſo. The whole ſcale of muſic is contained in one octave, and all the reſt are only repetitions of this ſcale. And thus is the doctrine of the ſcale of melody brought within a very moderate compaſs, and the problem is reduced to that of the repartition of a ſingle octave, and ſome attention to the junction with the ſimilar ſcales of the adjoining octaves. This partition is now to be the ſubject of diſcuſſion.

14
All muſic contained in the octave; hence called DIAPASON.

15
Melodies, or tunes, or airs, were the firſt muſic.

In the infancy of ſociety and cultivation, it is probable that the melodies or tunes, which delighted the ſimple inhabitants, were equally ſimple. Being the ſpontaneous effuſions of individuals, perhaps only occaſional, and never repeated. they would periſh as faſt as produced. The airs were probably connected with ſome of the rude rhimes, or gingles of words, which were bandied about at their feſtivals; or they were aſſociated with dancing. In all theſe caſes they muſt have been very ſhort, conſiſting of a few favourite paſſages or muſical phraſes. This is the caſe with the common airs of all ſimple people to this day. They ſeldom extend beyond a ſhort ſtanza of poetry, or a ſhort movement of dancing. The artiſt who could compoſe and keep in mind a piece of conſiderable length, muſt have been a great rarity, and a minſtrel fit for the entertainment of princes; and therefore much admired, and highly rewarded: his excellencies were almoſt incommunicable, and could not be preſerved in any other way but by repeated performance to an attentive hearer, who muſt alſo be an artiſt, and muſt patiently liſten, and try to imitate; or, in ſhort, to get the tune by heart. It muſt have been a long time before any diſtinct notion was formed of the relation of the notes to each other. It was perhaps impoſſible to recollect today the preciſe notes of yeſterday. There was nothing in which they were fixed till inſtrumental muſic was invented. This has been found in all nations; but it appears that long continued cultivation is neceſſary for raiſing this from a very ſimple and imperfect ſtate. The moſt refined inſtrument of the Greek muſicians was very far below our very ordinary inſtruments. And, till ſome method of notation was invented, we can ſcarcely conceive how any determined partition of the octave could be made generally known.

16
KEY-NOTE or FUNDAMENTAL.

Accordingly, we find that it was not till after a long while, and by very rude and awkward ſteps, that the Greeks perceived that the whole of muſic was compriſed in the octave. The firſt improved lyre had but four ſtrings, and was therefore called a TETRACHORD; and the firſt flutes had but three holes, and four notes; and when more were added to the ſcale, it was done by joining two lyres and two flutes together. Even this is an inſtructive ſtep in the hiſtory of muſical ſcience: For the four ſounds of the inſtrument have a natural ſyſtem, and the awkward and groping attempts to extend the muſic, by joining two inſtruments, the ſcale of the one following, or being a continuation of that of the other, pointed out the DIAPASON or *totality* of the octave, and the relation of the whole to a principal ſound, which we now call the *fundamental* or *key*, it being the loweſt note of our ſcale, and the one to which the other notes bear a continual reference. It would far exceed the limits of this Work to narrate the ſucceſſive changes and additions made by the Greeks in their lyre; yet would this be a very ſure way of learning the natural formation of our muſical ſcale. We muſt refer our readers to Dr Wallis's Appendix to his edition of the Commentary of Porphyrius in Ptolemy's Harmonics, as by far the moſt perſpicuous account that is extant of the Greek muſic. We ſhall pick out from among their different attempts ſuch plain obſervations as will be obvious to the feelings of any perſon who can ſing a common tune.

17
The octave is naturally divided into two TETRACHORDS.

Let ſuch a perſon firſt ſing over ſome plain and cheerful, or at leaſt not mournful, tune, ſeveral times, ſo as to retain a laſting impreſſion of the chief note of the tune, which is generally the laſt. Then let him begin, on the ſame note, to ſing in ſucceſſion the riſing ſteps of the ſcale, pronouncing the ſyllables *do, re, mi, fa, ſol, la, ſi, do*. He will perhaps obſerve, that this chaunt naturally divides itſelf into two parts or phraſes, as the muſicians term it. If he does not, of himſelf, make this remark, let him ſing it, however, in that manner, pauſing a little after the note *fa*. Thus, *do, re, mi, fa; ſol, la, ſi, do.—Do, re, mi, fa; ſol, la, ſi, do.*

Having done this ſeveral times, and then repeated it without a pauſe, he will become very ſenſible of the propriety of the pauſe, and of this natural diviſion of the octave. He will even obſerve a conſiderable ſimilarity between theſe two muſical phraſes, without being able, at firſt, to ſay in what it conſiſts.

18
The ſteps of the ſcale are unequal, and the two tetrachords are ſimilar.

Let him now ſtudy each phraſe apart, and try to compare the magnitude of the changes of ſound; or ſteps which he makes in riſing from *do* to *re*, from *re* to *mi*, and from *mi* to *fa*. We apprehend that he will have no difficulty in perceiving, after a few trials, that the ſteps *do re*, and *re mi*, are ſenſibly greater than the ſtep *mi fa*. We feel the laſt ſtep as a ſort of ſlide; as an attempt to make as little change of pitch as we can. Once this is perceived, it will never be forgotten. This will be ſtill more clearly perceived, if, inſtead of theſe ſyllables, he uſe only the vowel *a*, pronounced as in the word *ball*, and if he ſing the ſteps, ſliding or ſlurring from the one to the other. Taking this method, he cannot fail to notice the ſmallneſs of the third ſtep.

19
Let the ſinger farther conſider, whether he does not feel this phraſe muſical or agreeable, making a ſort of tune or chaunt, and ending or cloſing agreeably after this ſlide of a ſmall, or, as it were, half ſtep. It is generally thought ſo; and is therefore called a CLOSE, a CADENCE, when we end with a half ſtep aſcending.

20
Let the ſinger now reſume the whole ſcale, ſinging the four laſt notes *ſol, la, ſi, do,* louder than the other four, and calling off his attention from the low phraſe, and fixing it on the upper one. He will now be able to perceive that this, like the other, has two conſiderable ſteps; namely, *ſol la* and *la ſi*, and then a ſmaller ſtep, *ſi do*. A few repetitions will make this clear, and he will then be ſenſible of the nature of the ſimilarity between theſe two phraſes, and the propriety of this great diviſion of the ſcale into the intervals *do, fa*, and *ſol, do*, with an interval *fa, ſol* between them.

This was the foundation of the tetrachords, or lyres of four ſtrings, of the Greeks. Their earlieſt muſic or modulation ſeems to have extended no farther than this phraſe. It pleaſed them, as a ring of four bells pleaſes many country pariſhes.

21
CLOSE or CADENCE.

The ſinger will perceive the ſame ſatisfaction with the cloſe of this ſecond phraſe as with that of the former: and if he now ſing them both, in immediate ſucceſſion,

Temperament of the Scale of Muſic.

ſucceſſion, with a ſlight pauſe between, we imagine that he will think the cloſe or cadence on the upper *do* even more ſatisfactory than that on the *fa*. It ſeems to us to complete a tune. And this impreſſion will be greatly heightened, if another perſon, or an inſtrument, ſhould ſound the lower *do*, while he cloſes on the upper *do* its octave. *Do* ſeems to be expected, or looked for, or ſought after. We take *ſi* as a ſtep to *do*, and there we reſt.

22
The third and ſeventh ſtep are the ſmalleſt.

Thus does the octave appear to be naturally compoſed of ſeven ſteps, of which the firſt, ſecond, fourth, fifth, and ſixth, are more conſiderable, and the third and ſeventh very ſenſibly ſmaller. Having no direct meaſures of their quantity, nor even a very diſtinct notion of what we mean by their quantity, magnitude, or bulk, we cannot pronounce, with any certainty, whether the greater ſteps are equal or unequal; and we preſume them to be equal. Nor have we any diſtinct notion of the proportion between the larger and ſmaller ſteps. In a looſe way we call them half notes, or ſuppoſe the riſe from *mi* to *fa*, or from *ſi* to *do*, to be one-half of that from *do* to *re*, or from *re* to *mi*.

23
The Pythagorean diſcoveries did not improve the Greek muſic.

Accordingly, this ſeems to have been all the muſical ſcience attained by the Greek artiſts, or thoſe who did not profeſs to ſpeak philoſophically on the ſubject. And even after Pythagoras publiſhed the diſcovery which he had made, or more probably had picked up among the Chaldeans or Egyptians, by which it appeared, that accurate meaſures of ſounds, in reſpect to gravity and acuteneſs, were attainable, it was affirmed by Ariſtoxenus, a ſcholar of Ariſtotle, and other eminent philoſophers, that theſe meaſures were altogether artificial, had no connection with muſic, and that the ear alone was the judge of muſical intervals. The artiſt had no other guide in tuning his inſtrument; becauſe the ratios, which were ſaid to be inherent in the ſounds (though no perſon could ſay how), were never perceived by the ear. The juſtice of this opinion is abundantly confirmed by the awkward attempt of the Greeks to improve the lyre by means of theſe boaſted ratios. Inſtead of illuſtrating the ſubject, they ſeem rather to have brought an additional obſcurity upon it, and threw it into ſuch confuſion, that although many voluminous diſſertations were written on it, and on the compoſition of their muſical ſcale, the account is ſo perplexed and confuſed, that the firſt mathematicians and artiſts of Europe acknowledge, that the whole is an impenetrable myſtery. Had the philoſophers never meddled with it, had they allowed the practical muſicians to conſtruct and tune their inſtruments in their own way, ſo as to pleaſe their ear, it is ſcarcely poſſible that they ſhould not have hit on what they wanted, without all the embarraſſment of the chromatic and enharmonic ſcales of the lyre. It is ſcarcely poſſible to contrive a more cumberſome method of extending the ſimple ſcale of Nature to every caſe that could occur in their muſical compoſitions, than what aroſe from the employment of the muſical ratios. This ſeems a bold aſſertion; but we apprehend that it will appear to be juſt as we proceed.

24
The tranſpoſition of muſic made intercalary notes neceſſary in the octave.

The practical muſicians could not be long of finding the want of ſomething more than the mere diatonic ſcale of their inſtruments. As they were always accompanied by the voice, it would often happen that a lyre or flute, perfectly tuned, was too low or too high for the voice that was to accompany it. A ſinger can pitch his tune on any ſound as a key; and if this be too high for the ſinger who is to accompany him, he can take it on a lower note. But a lyriſt cannot do this. Suppoſe his inſtrument two notes too low, and that his accompanyiſt can only ſing it on the key which is the *ſi* of the lyre. Should the lyriſt begin it on that key, his very firſt ſtep is wrong, being but a half ſtep, whereas it ſhould be a whole one. In ſhort, all the ſteps but one will be found wrong, and the lyriſt and ſinger will be perpetually jarring. This is an evident conſequence of the inequality of the fourth and ſeventh ſteps to the reſt. And if the other ſteps, which we imagine to be equal, be not exactly ſo, the diſcordance will be ſtill greater.

Diſputes of the Pythagoreans and Ariſtoxenians about muſical intervals.

The method of remedying this is very obvious. If the intervals *mi fa* and *ſi do*, are half notes, we need only to interpoſe other ſounds in the middle between each of the whole notes; and then, in place of ſeven unequal ſteps, we ſhall have twelve equal ones, or twelve intervals, each of them equal to a ſemitone. The lyre thus conſtructed will now ſuit any voice whatever. It will perfectly reſemble our keyed inſtruments, the harpſichord, or organ, which have twelve ſeemingly equal intervals in the octave. Accordingly, it appears that ſuch additions were practiſed by the muſicians of Greece, and approved of by Ariſtoxenus, and by all thoſe who referred every thing to the judgment of the ear. And we are confident that this method would have been adopted, if the philoſophers had had leſs influence, or if the Greeks had not borrowed their religious ceremonies along with their muſical ſcience. Both of theſe came from the ſame quarter; they came united; and it was ſacrilegious to attempt innovations. The doctrine of muſical ratios was an occupation only for the refined, the philoſophers; and by ſubjecting muſic to this myſterious ſcience, it became myſterious alſo, and ſo much the more venerable. The philoſophers ſaw, that there was in Nature a certain inſcrutable connection between mathematical ratios and thoſe intervals which the ear reliſhed and required in melody: but they were ignorant of the nature and extent of this connection.

Ratios of octave, diapente, and diateſſaron.

What is this connection, or what is meant when we ſpeak of the ratios of ſounds? Simply this:—Pythagoras is ſaid to have found, that if two muſical cords be ſtrained by equal weights, and one of them be twice the length of the other, the ſhort one will ſound the octave to the note of the other. If it be two-thirds of the length of the long ſtring, it will ſound the fifth to it. If the long ſtring ſound *do*, the ſhort one will ſound *ſol*. If it be three-fourths of the length, it will ſound the fourth or *fa*. Thus the ratio of 2 : 1 was called the ratio of the DIAPASON; that of 3 : 2 was called the DIAPENTE; and that of 4 : 3 the DIATESSARON. Moreover, if we now take all the four ſtrings, and make that which ſounds the graveſt note, and is the longeſt, twelve inches in length; the ſhort or octave ſtring muſt be ſix inches long, or one-half of twelve; the diapente muſt be eight inches, or two-thirds of twelve; and the diateſſaron muſt be nine inches, which is three-fourths of twelve. If we now compare the diapente, not with the graveſt ſtring, but with the octave of ſix inches, we ſee that they are in the ratio of 4 to 3, or the ratio of diateſſaron. And if we compare the diateſſaron with the

Temperament of the Scale of Music.

the octave, we see that their ratio is that of 9 : 6, or of 3 : 2, or the ratio of diapente. Thus is the octave divided into a fifth and a fourth, *do sol*, and *sol do*, in succession. Also the fourth *do fa*, and the fifth *fa do*, make up the octave. The note which stands as a fifth to one of the extreme sounds of the octave, stands as a fourth to the other. And, lastly, the two fourths *do fa*, and *sol do*, leave an interval *fa sol* between them; which is also determined by nature, and the ratio corresponding to it is evidently that of 9 to 8.

The discovery of Pythagoras is called a fable, or fabulously narrated.

This is all that was known of the connection of music with mathematical ratios. It is indeed said by Iamblichus, that Pythagoras did not make this discovery by means of strings, but by the sounds made by the hammers on the anvil in a smith's shop. He observed the sounds to be the key, the diatessaron, and the diapente of music; and he found, that the weights of the hammers were in this proportion; and as soon as he went home, he tried the sounds made by cords, when weights, in the proportions above mentioned, were appended to them. But the whole story has the air of a fable, and of ignorance. The sounds given by a smith's anvil have little or no dependence on the weight of the hammers; and the weights which are in the proportions of the numbers mentioned above will by no means produce the sounds alleged. It requires *four* times the weight to make a string sound the octave, and *twice and a quarter* will produce the diapente, and *one and seven-ninths* will produce the diatessaron. It is plain, therefore, that they knew not of what they were speaking: yet, on this slight foundation, they erected a vast fabric of speculation; and in the course of their researches, these ratios were found to contain all that was excellent. The attributes of the Divinity, the symmetry of the universe, and the principles of morality, were all resolvable into the harmonic ratios.

26
Conjoined and disjoined tetrachords.

In the attempts to explain, by means of the mysterious properties of the ratios 2 : 1, 3 : 2, 4 : 3, and 9 : 8, which were thus defined by Nature, it was observed, that their favourite lyres of four strings could be combined in two principal manners, so as to produce an extensive scale. One lyre may contain the notes *do, re, mi, fa*; and the acuter lyre may contain the notes *sol, la, si, do*; and, being set in succession, having the interval *fa sol* between the highest note of the one and the lowest of the other, they make a complete octave. These were called *disjoined tetrachords*. Again, a third tetrachord may be joined with the upper tetrachord last mentioned, in such sort, that the lowest note of the third tetrachord may be the same with the highest of the second. These were called *conjoined* tetrachords (A).

The lyres were tuned chiefly by the ear,

By thus considering the scale as made up of tetrachords, the tuning of the lyre was reduced to great simplicity. The musician had only to make himself perfect in the short chaunt *do, re, mi, fa*, or to get it by heart, and to sing it exactly. This intonation would apply equally to the other *sol, la, si, do*. We are well informed that this was really the practice. The directions given by Aristoxenus, Nicander, and others, for varying the tuning, according to certain occasional accommodations, shew distinctly that they did not tune as we do, sounding the two strings together, except in the case of the diapason or octave. It was all done by the judgment of the ear in melody. The most valuable circumstance in the discovery of Pythagoras was the determination of the interval between the fourth and the fifth, by which the tetrachords were separated. The filling up of each tetrachord was left entirely to the ear; and when the doctrine of the mathematical ratios shewed that the large intervals *do re, re mi, fa sol, sol la, la si*, should not be precisely equal, Aristoxenus refused the authority of the reasons alleged for this inequality, because the ear perceived none of the ratios as ratios, and could judge only of sounds. He farther asserted, that the inequalities which the Pythagoreans enjoined, were so trifling, that no ear could possibly perceive them. And accordingly, the theorists disputed about the respective situations of the greater and smaller tones (so they named the great steps) so much spoken of, and had different systems on the subject.

And by melody alone: 28

But the strongest proof of the indistinct notion that the theorists entertained about the influence of these ratios in music is, that they would admit no more but those introduced by Pythagoras; and their reasons for the rejection of the ratio of 5 to 4, and of 6 to 5, were either the most whimsical fancies about the perfections of the sacred ratios, or assumptions expressly founded on the supposition, that the ear perceives and judges of the ratios as ratios; than which nothing can be more false. Had they admitted the ratio of 5 to 4, they would have obtained the third note of the scale, and would at once have gotten the whole scale of our music. The ratios of 6 : 5, and 16 : 15, follow of course; and every sound of the tetrachords would have been determined. For 5 : 4 being the ratio of the major third, which is perfectly pleasing to the ear, as the *mi* to the note *do*, and 3 : 2 being the ratio of the fifth *do sol*, there is another interval *mi sol* determined; and this ratio, being the difference between *do sol* and *do mi*, or between 3 : 2 and 5 : 4, is evidently 6 : 5. In like manner, the interval *mi fa* is determined, and its ratio, being 4 : 3 — 5 : 4, is 16 : 15.

But farther; we shall find, upon trial, that if we put in a sound above *sol*, having the relation 5 : 4 to *fa*, it will be perfectly satisfactory to the ear if sung as the note *la*. And if, in like manner, we put in a note above *la*, having the relation 5 : 4 to *sol*, we find it satisfactory to the ear when used as *si*. If we now examine the ratios of these artificial notes, we shall find the ratio of the notes *sol la* to be 10 : 9, and that of *la si* to be 9 : 8, the same with that *fa sol*; also *si do* will appear to be 16 : 15, like that of *mi fa*.

We have no remains of the music of the Greeks, by which we can learn what were their favourite passages or musical phrases; and we cannot see what caused them to prefer the fourth to the major third. Few musicians of our times think the fourth in any degree comparable with the major third for melodiousness, and still fewer for harmoniousness. The piece or tune published by Kircher from Alypius is very suspicious, as no

(A) This is the *principle*, but not the precise *form*, of the disjoined and conjunct tetrachords. The Greeks did not begin the tetrachord with what we make the first note of our chaunt of four notes, but began one of them with *mi*, and the other with *si*; to which they afterwards added a note below. This beginning seems to have been directed by some of their favourite cadences; but it would be tedious to explain it.

Temperament of the Scale of Music.

no other person has seen the MS; and the collection found at Buda is too much disfigured, and probably of too late a date, to give us any solid help. In all probability, the common melodies of the Greeks abounded in easy leaps up and down on the third and fifth, and on the fourth and sixth, just as we observe in the airs for dancing among all simple people. Their accomplished performers had certainly great powers both of invention and execution; and the chromatic and enharmonic divisions of the scale were certainly practised by them, and not merely the speculations of mathematicians. To us, the enharmonic scale appears the most jarring discord; but this is certainly owing to our not seeing any pieces of the music so composed, and because we cannot in the least judge by harmony what the effect of enharmonic melody would be. But we have sufficient from the writings of the ancient Greeks, that the enharmonic music fell into disuse even before the time of Ptolemy, and was totally and irrecoverably lost before the 5th century. Even the chromatic was little practised, and was chiefly employed for extending the common scale to keys which were seldom used. The uncertainties respecting even the common scale remained the same as ever; and although Ptolemy gives (among others) the very same that is now admitted as the only perfect one, namely, his *diatonicum intensum*, his reasons of preference, though good, are not urged with strong marks of his confidence in them, nor do they seem to have prevailed.

29 But melody is quite insufficient.

These observations shew clearly, that the perception of melody alone is not sufficiently precise for enabling us to acquire exact conceptions of the scale of music. The whole of the practicable science of the ancients seems to amount to no more than this, that the octave contained five greater and two smaller intervals, which the voice employed, and the ear relished. The greater intervals seemed all of one magnitude; and the smaller intervals appeared also equal, but the ear cannot judge what proportion they bear to the larger ones. The musicians thought them larger than one-half of the great intervals (and indeed the ratio 16 : 15 of the artificial *mi fa* and *si do*, is greater than the half of 9 : 8 or 10 : 9). Therefore they allowed the theorists to call them *limmas* instead of *hemitones*; but they, as well as the theorists, differed exceedingly in the magnitudes which they assigned them.

30 Circular representation of the scale. Plate XLIV

The best way that we can think of for expressing the scale of the octave is, by dividing the circumference of a circle in the points C, D, E, F, G, A, and B (fig. 1.), in the proportion we think most suitable to the natural scale of melody. According to the practical notion now under our consideration, the arches CD, DE, FG, GA, and AB, are equal, containing nearly 59°; and the arches EF and BC are also equal, but smaller than the others, containing about 33½. Now, suppose another circle, on a piece of card paper, divided in the same manner, to move round their common centre, but instead of having its points of division marked C, D, E, &c. let them be marked *do, re, mi, fa, sol, la, si*. It is plain, that to whatever point of the outer circle we set the point *do* of the inner one, the other points of the outer circle will shew the common notes which are fit for those steps of the scale. The similarity of all octaves makes this simple octave equivalent to a rectilineal scale similarly divided, and repeated as often as we please. Fig. 1. represents this instrument, and will be often referred to. A sort of symmetry may be observed in it. The point D seems to occupy the middle of the scale, and *re* seems to be the middle note of the octave. The opposite arch GA, and the corresponding interval *sol la*, seems to be the middle interval of the octave. The other notes and intervals are similarly disposed on each side of these. This circumstance seems to have been observed by the Greeks, by the inhabitants of India, by the Chinese, and even by the Mexicans. The note *re*, and the interval *sol la*, have gotten distinguished situations in their instruments and scales of music.

31 Aristoxenean division of the circle.

With respect to the division of the circles, we shall only observe at present, that the dotted lines are conformable to the principles of Aristoxenus, the whole octave being portioned out into five larger and equal intervals, and two smaller, also equal. The larger are called *mean* or *medium tones*; and the smaller are called *limmas* or *semitones*. The full lines, to which the letters and names are affixed, divide the octave into the artificial portions, determined by means of the musical ratios, the arches being made proportional to the measures of those ratios. Thus the arches CD, FG, AB, are proportional to the measure or logarithm of the ratio 9 : 8; GA and DE are proportional to the logarithm of 10 : 9; and the arches EF and BC are proportional to the logarithm of 16 : 15. We have already mentioned the way in which those ratios were applied, and the authority on which they were selected. We shall have occasion to return to this again. The only farther remark that is to be made with propriety in this place is, that the division on the Aristoxenean principles, which is expressed in this figure, is one of an indefinite number of the same kind. The only principle adopted in it is, that there shall be five mean tones, and two small equal semitones; but the magnitude of these is arbitrary. We have chosen such, that two mean tones are exactly equal to the arch CE, determined by the ratio 5 : 4. The reasons for this preference will appear as we proceed (B).

By this little instrument (the invention, we believe, of a Mr D'Ormisson, about the beginning of last century), we see clearly the insufficiency of the seven notes of the octave for performing music on different keys. Set the flower de luce at the Aristoxenean B, and we shall see that E is the only note of our lyre which will do for one of the steps of the octave in which we intend to sing and accompany. We have no sounds in the lyre for *re, mi, sol, la, si*. The remedy is as clearly pointed out. Let a set of strings be made, having the same relation to *si* which those of the present lyre have to *do*, and insert them in the places pointed out by the Aristoxenean divisions of the moveable octave. We need only five of them, because the *si* and *fa* of the present lyre will answer. These new sounds are marked by a +.

32 Found imperfect and determinate.

But it was soon found, that these new notes gave but indifferent melody, and that either the ear could not determine

(B) We shall be abundantly exact, if we make CD = 61°,72; CE = 115°,9; CF = 149°,42; CG = 210°,58; CA = 263°,3; and CB = 326°,48.

Temperament of the Scale of Music.

determine the equality of the tones and ſemitones exactly enough, or that no ſuch partition of the octave would anſwer. The Pythagoreans, or partiſans of the muſical ratios, had told them this before. But they were in no better condition themſelves; for they found, that if a ſeries of ſounds, in perfect relation to the octave, be inſerted in the manner propoſed, the melody will be no better. They put the matter to a very fair trial. It is eaſy to ſee, that no ſyſtem of mean tones and limmas will give the ſame muſic on every key, unleſs the tones be increaſed, and the limmas diminiſhed, till the limma becomes juſt half a tone. Then all the intervals will be perfectly equal. The mathematicians computed the ratios which would produce this equality, and deſired the Ariſtoxeneans to pronounce on the muſic. It is ſaid, that they allowed it to be very bad in all their moſt favourite paſſages. Nothing now remained to the Ariſtoxeneans but to attempt occaſional methods of tuning. They ſaw clearly, that they were making the notes unequal which Nature made equal. The Pythagoreans, in like manner, pointed out many alterations or corrections of intervals which ſuited one tetrachord, or one part of the octave, but did not ſuit another. Both parties ſaw that they were obliged to deviate from what they thought natural and perfect: therefore they called theſe alterations of the natural or perfect ſcale a *temperament*.

The accompliſhed performers were the beſt judges of the whole matter, and they derived very little aſſiſtance from the mathematicians: For although the rigid rules delivered by them be acknowledged to be perfectly exact, the execution of thoſe rules is not ſuſceptible of the ſame exactneſs. Their lyres are tuned, not by mathematical operations, but by the ear. It does not appear that they had muſical inſtruments with divided finger-boards, like our baſs viols and guitars; and even on theſe, it is well known that the preſſure and touch of the finger may vary ſo much, that the moſt exact placing of the frets will not inſure the nice degrees of the ſounds. The flutes are the only inſtruments of the ancients that are capable of accurate ſounds. But flutemakers know very well, that they cannot be tuned by mathematical operations, but by the ear alone. This accounts for the great prices paid for a well-tuned flute. Some have coſt L. 700, and L. 50 was a very common price.

33 The Greeks did not cultivate the harmony of ſimultaneous ſounds.

Such ſeems to have been the ſtate of the ancient muſic. There was little or no ſcience in it. There was, indeed, a moſt abſtruſe and refined ſcience coupled with it; but by a very ſlight connection: and it ſeems to have been nothing more than an amuſement for the ingenious and ſpeculative Greeks. Nor could it, in our opinion, be better, ſo long as they had no guide in tuning but the judgment of the ear in melody. Many writers inſiſt that the Greeks had a knowledge of what *we* call *harmony* alſo. The word ἁρμονια is conſtantly uſed by them: but it does not mean what we call harmony, the pleaſant coaleſcence of ſimultaneous ſounds. It comes from ἁρμος, or from ἁρμοζω, and ſignifies *aptitude, fitneſs*, and would, in general, be better tranſlated by *ſymmetry*. But we cannot conceive that they paid any marked attention to the effect of ſimultaneous ſounds, ſo as to enjoy the pleaſure of certain conſonances, and employ them in their compoſitions. We judge in this way from the rank which they gave them in their ſcale. To prefer the fourth to the major third ſeems to us to be impoſſible, if it be meant of ſimultaneous ſounds. And the reaſon which is aſſigned for the preference can have no value in the opinion of a muſician. It is becauſe the ratio of 4 : 3 is ſimpler than that of 5 : 4. For the ſame reaſon, the fifth is preferred to both, and the octave to all the three, and uniſon to every other conſonance. They would not allow the major third 5 : 4 to be a concord at all. We have made numberleſs trials of the different concords with perſons altogether ignorant of muſic. We never ſaw an inſtance of one who thought that mere uniſon gave any poſitive pleaſure. None of all whom we examined had much pleaſure from an octave. All, without exception, were delighted with a fifth, and with a major third; and many of them preferred the latter. All of them agreed in calling the pleaſure from the fifth a *ſweetneſs*, and that from the major third a *cheerfulneſs*, or *ſmartneſs*, or by names of ſimilar import. The greater part preferred even the major ſixth to the fourth, and ſome felt no pleaſure at all from the fourth. Few had much pleaſure from the minor third or minor ſixth. *N. B.* Care was taken to ſound theſe concords without any preparation—merely as ſounds—but not as making part of any muſical paſſage. This circumſtance has a great effect on the mind. When the minor third and ſixth were heard as making part of the minor mode, all were delighted with it, and called it ſweet and mournful. In like manner, the chord $\frac{6}{4}$ never failed to give pleaſure. Nothing can be a ſtronger proof of the ignorance of the ancients of the pleaſures of harmony.

34 The pleaſures of harmony ſeem to be a modern diſcovery.

We do not profeſs to know when this was diſcovered. We think it not unlikely that the Greeks and Italians got it from ſome of the northern nations whom they called *Barbarians*. We cannot otherwiſe account for its prevalence through the whole of the Ruſſian empire—the ancient Slavi had little commerce with the empire of Rome or of Conſtantinople; yet they ſung in parts in the moſt remote periods of their hiſtory of which we have any account; and to this day, the moſt uncultivated boor in the Ruſſian empire would be aſhamed to ſing in uniſon. He liſtens a little while to a new tune, holding his chin to his breaſt; and as ſoon as he has got a notion of it, he burſts out in concert, throwing in the harmonic notes by a certain rule which he feels, but cannot explain. His harmonics are generally alternate major and minor thirds, and he ſeldom miſſes the proper cadences on the fifth and key. Perhaps the invention of the organ produced the diſcovery. We know that this was as early as the ſecond century (c). It was hardly poſſible to make much uſe of that inſtrument without perceiving the pleaſure of concordant ſounds.

The

(c) It is ſaid that the Chineſe had an inſtrument of this kind long before the Europeans. Cauſeus ſays, that it was brought from China by a native, and was ſo ſmall as to be carried in the hand. It is certain that the Emperor Conſtantine Copronymus ſent one to Pepin king of France in 757, and that his ſon Charlemagne got another from the Emperor Michael Paleologus. But they appear to have been known in the Engliſh churches before that time.

Temperament of the Scale of Music.

35 Harmony made a great change in the science of music.

The discovery of the pleasures of harmony occasioned a total change in the science of music. During the dark ages of Europe, it was cultivated chiefly by the monks: the organ was soon introduced into the churches, and the choral service was their chief and almost their only occupation. The very construction of this instrument must have contributed to the improvement of music, and instructed men in the nature of the scale. The pipes are all tuned by their lengths; and these lengths are in the ratios of the strings which give the same notes, when all are equally stretched. This must have revived the study of the musical ratios. The tuning of the organ was performed by consonance, and no longer depended on the nice judgment of sounds in succession. The dullest ear, even with total ignorance of music, can judge, without the smallest error, of an exact octave, fifth, third, or other concord; and a very mean musician could now tune an organ more accurately than Timotheus could tune his lyre. Other keyed instruments, resembling our harpsichord, were invented, and instruments with fretted finger boards. These soon supplanted the lyres and harps, being much more compendious, and allowing a much greater variety and rapidity of modulation. All these instruments were the fruits of harmony, in the modern sense of that word. The deficiences of the old diatonic scale were now more apparent, and the necessity of a number of intercalary notes. The finger-board of an organ or harpsichord, running through a series of octaves, and admitting much more than the accompanyment of one note, pointed out new sources of musical pleasure arising from the fulness of the harmoy; and, above all, the practice of choral singing suggested the possibility of a pleasure altogether new. While a certain number of the choir performed the Cantus or Air of the music, it was irksome to the others to utter mere sounds, supporting or composing the harmony of the Cantus, without any melody or air in their own parts. It was thought probable that the harmonic notes might be so portioned out among the rest of the choir, that the succession of sounds uttered by each individual might also constitute a melody not unpleasant, and perhaps highly grateful. On trial, it was found very practicable. Canons, motets, fugues, and other harmonies, were composed, where the airs performed by the different parts were not inferior in beauty to the principal. The notes which could not be thrown into this agreeable succession, were left to the organist, and by him thrown into the bass.

36. By all these practices, the imperfections of the scale of fixed sounds became every day more sensible, especially in full harmony. Scientific music, or the properties of the ratios, now recovered the high estimation in which they were held by the ancient theorists; and as the musicians were now very frequently men of letters, chiefly monks, of sober characters and decent manners, music again became a respectable study. The organist was generally a man of science, as well as a performer. At the first revival of learning in Europe, we find music studied and honoured with degrees in the universities, and very soon we have learned and excellent dissertations on the principles of the science. The inventions of Guido, and the dissertations of Salinas, Zarlino, and Xoni, are among the most valuable publications that are extant on music. The improvements introduced by Guido are founded on a very refined examination of the scale; and the temperaments proposed by the other two have scarcely been improved by any labours of modern date. Both these authors had studied the Greek writers with great care, and their improvements proceed on a complete knowledge of the doctrines of Pythagoras and Ptolemy.

37 Galileo's [illegible]

At last the celebrated Galileo Galilei put the finishing hand to the doctrines of those ancient philosophers, by the discovery of the connection which subsists in nature between the ratios of numbers and the musical intervals of sounds. He discovered, that these numbers express the frequency of the recurring pulses or undulations of air which excite in us the sensation of sound. He demonstrated that if two strings, of the same matter and thickness, be stretched by equal weights, and be twanged or pinched so as to vibrate, the times of their vibrations will be as their lengths, and the frequency or number of oscillations made in a given time will be inversely as their lengths. The frequency of the sonorous undulations of the air is therefore inversely as the length of the string. When therefore we say that 2 : 1 is the ratio of the octave, we mean, that the undulations which produce the upper sound of this interval are twice as frequent as those which produce its fundamental sound. And the ratio 3 : 2 of the diapente or fifth, indicates, that in the same time that the ear receives three undulations from the upper sound, it receives only two from the lower. Here we have a natural connection, not peculiar to the sounds produced by strings; for we are now able to demonstrate, that the sounds produced by bells are regulated by the same law. Nay, the improvements which have been made in the science of motion since the days of Galileo, shew us that the undulations of the air in pipes, where the air is the *only* substance moved, is regulated by the same law. It seems to be the general property of sounds which renders them susceptible of musical pitch, of acuteness, or gravity; and that a certain frequency of the sonorous undulations gives a determined and unalterable musical note. The writer of this article has verified this by many experiments. He finds, that *any noise whatever*, if repeated 240 times in a second, at equal intervals, produces the note C *sol fa ut* of the Guidonian gamut. If it be repeated 360 times, it produces the G *sol re ut*, &c. It was imagined, that only certain regular agitations of the air, such as are produced by the tremor or vibration of elastic bodies, are fitted for exciting in us the sensation of a musical note. But he found, by the most distinct experiments, that any noise whatever will have the same effect, if repeated with due frequency, not less than 30 or 40 times in a second. Nothing surely can have less pretension to the name of a musical sound than the solitary snap which a quill makes when drawn from one tooth of a comb to another: but when the quill is held to the teeth of a wheel, whirling at such a rate, that 720 teeth pass under it in a second, the sound of *g in alt.* is heard most distinctly; and if the rate of the wheel's motion be varied in any proportion, the noise made by the quill is mixed in the most distinct manner with the musical note corresponding to the frequency of the snaps. The *kind* of the original noise determines the kind of the continuous sound produced by it, making it harsh and fretful, or smooth and mellow, according as the original noise is abrupt or gradual: but even the most abrupt noise

Temperament of the Scale of Music.

noise produces a tolerably smooth sound when sufficiently frequent. Nothing can be more abrupt than the snap just now mentioned; yet the *g* produced by it has the smoothness of a bird's chirrup. An experiment was made, which was less promising of a sound than any that can be thought of. A stop cock was so constructed, that it opened and shut the passage through a pipe 720 times in a second. This apparatus was fitted to the pipe of a conduit leading from the bellows to the wind chest of an organ. The air was simply allowed to pass gently along this pipe by the opening of the cock. When this was repeated 720 times in a second, the sound *g in alt.* was most smoothly uttered, equal in sweetness to a clear female voice When the frequency was reduced to 360, the sound was that of a clear but rather harsh man's voice. The cock was now altered in such a manner, that it never shut the hole entirely, but left about one third of it open. When this was repeated 720 times in a second, the sound was uncommonly smooth and sweet. When reduced to 360, the sound was more mellow than any man's voice at the same pitch. Various changes were made in the form of the cock, with the intention of rendering the primitive noise more analogous to that produced by a vibrating string. Sounds were produced which were pleasant in the extreme. The intelligent reader will see here an opening made to great additions to practical music, and the means of producing musical sounds, of which we have at present scarcely any conception; and this manner of producing them is attended with the peculiar advantage, that an instrument so constructed can never go out of tune in the smallest degree. But of this enough at present.

38 This frequency is express'd by the musical ratios of Pythagoras.

This discovery of Galileo's completed the Pythagorean theories, by supplying the only thing wanted for procuring confidence in them. We now see that the music of sounds depends on principles as certain and as plain as the elements of Euclid, and that every thing relating to the scale of music is attainable by mathematics. It is very true that we do not perceive the ratio 3 : 2 in the diapente, as having any relation to the numbers 3 and 2. But we perceive the sweetness of sound which characterises this concord. This is undoubtedly the perception of a certain physical fact involving this ratio, as much as the sweetness on our tongue is the perception of a certain manner of acting of the particles of sugar during their dissolution in the saliva.

Concord, discord, are properties of particular ratios of frequency

The pleasure arising from certain consonances, such as *do sol*, is not more distinctly perceived than is the disagreeable feeling which other consonances produce, such as *do re*; and it was a fair field of disquisition to discover why the one pleased and the other displeased. We cannot say that this question has been completely decided. It has been ascribed to the coincidence of vibrations. In the octave, every second vibration of the treble note may be made to coincide with every vibration of the bass. But the pleasure arising from the different consonances does by no means follow the proportions of these coincidences of vibrations; for when two notes are infinitely near to the state which would produce a complete coincidence, the actual coincidence is then exceedingly rare; and yet we know that such sounds yield very fine harmony. In tuning any concord, when the two notes are very discordant, the coinciding vibrations recur very frequently; and as we approach nearer and nearer to perfect concord, these coincidences become rarer and rarer; and if it be infinitely near to perfect concord, the coincidences of vibration will be infinitely distant from each other. This, and many other irrefragable arguments, demonstrate that coalescence of sound, which makes the pleasing harmony of a fifth, for example, does not arise from the coincidence of vibrations; and the only thing which we can demonstrate to obtain in all the cases where we enjoy this pleasure, is a certain arrangement of the component pulses, and a certain law of succession of the dislocations or intervals between the non-coinciding pulses. We are perfectly able to demonstrate that when, by continually screwing up one of the notes of a consonance, we render the real coincidence of pulses less frequent; the dislocations, or deviations from perfect coincidence, approach nearer and nearer to a certain defineable law of succession; and that this law obtains completely, when the perfect ratio of the duration of the pulse is attained, although perhaps at that time not one pulse of the one sound coincides with a pulse of the other. Suppose two organ pipes, sounding the note C *sol fa ut*, at the distance of ten feet from each other, and that their pulses begin and end at the same instants, making the most perfect coincidence of pulses—there is no doubt but that there will be the most perfect harmony; and we learn by experience that this harmony is perfectly the same, from whatever part of the room we hear it. This is an unquestionable fact. A person situated exactly in the middle between them will receive coincident pulses. But let him approach one foot nearer to one of the pipes, it is now demonstrable that the pulses, at their arrival at his ear, will be the most distant from coincidence that is possible; for every pulse of one pipe will bisect the pulse from the other: but the law of succession of the deviations from coincidence will then obtain in the most perfect manner. A musical sound is the sensation of a certain form of the aerial undulation which agitates the auditory organ. The perception of harmonious sound is the sensation produced by another definite form of the agitation. This is the composition of two other agitations; but it is the compound agitation only that affects the ear, and it is its form or kind which determines the sensation, making it pleasant or unpleasant.

Hence arises the great use of mathematics in music. 39

Our knowledge of mechanics enables us to describe this form, and every circumstance in which one agitation can differ from another, and to discover general features or circumstances of resemblance, which, in fact, accompany all perceptions of harmony. We are surely intitled to say that these circumstances are sure tests of harmony; and that when we have ensured their presence, we have ensured the hearing of harmony in the adjusted sounds. We can even go farther in some cases: We can explain some appearances which accompany imperfect harmony, and perceive the connection between certain distinct results of imperfect coincidences, and the magnitude of the deviations from perfect harmony which are then heard. Thus, we can make use of these phenomena, in order to ascertain and measure those deviations; and if any rules of temperament should require a certain determinate deviation from perfect harmony in the tuning of an instrument, we can secure the appearance of that phenomenon which corresponds to the deviation, and thus can produce the precise temperament

Temperament of the Scale of Music.

rament suggested by our rules. We can, for example, destroy the perfect harmony of the fifth C *g*, and flatten the note *g* till it deviates from a perfect fifth in the exact ratio of 320 to 321, which the musicians call the one-fourth of a comma. The most exquisite ear for melody is almost insensible of a deviation four times greater than this; and yet a person who has no musical ear at all, can execute this temperament by the rules of harmony without the error of the fortieth part of a comma.

40
Beatings of imperfect consonances.

For this most valuable piece of knowledge we are indebted to the late Dr Robert Smith of Cambridge, a very eminent geometer and philosopher, and a good judge of music, and very pleasing performer on the organ and harpsichord. This gentleman, in his Dissertation on the Principles of Harmonics, published for the first time in 1749, has paid particular attention to a phenomenon in coexistent sounds, called a *beating*. This is an alternate enforcement and diminution of the strength of sound, something like what is called a close shake, but differing from it in having no variation in the pitch of the sounds. It is a sort of undulation of the sound, in which it becomes alternately louder and fainter. It may be often perceived in the sound of bells and musical glasses, and also in the sounds of particular strings. It is produced in this way: Suppose two unisons quite perfect; the vibrations of each are either perfectly coincident, or each pulse of one sound is interposed in the same situation between each pulse of the other. In either case they succeed each other with such rapidity, that we cannot perceive them, and the whole appears an uniform sound. But suppose that one of the sounds has 240 pulses in a second, which is the undulation that is produced in a pipe of 24 inches long; suppose that the other pipe is only 23 inches and $\frac{7}{10}$ths long. It will give 243 pulses in a second. Therefore the 1st, the 80th, the 160th, and the 240th pulse of the first pipe will coincide with the 1st, the 81st, the 162d, and the 243d pulse of the other. In the instants of coincidence, the agitation produced by one pulse is increased by that produced by the other. The commencement of the next two pulses is separated a little, and that of the next is separated still more, and so on continually: the *dislocations* of the pulses, or their deviations from perfect coincidence, continually increasing, till we come to the 40th pulse of the one pipe, which will commence in the middle of the 41st pulse of the other pipe; and the pulses will now bisect each other, so that the agitations of the one will counteract or weaken those of the other. Thus the compounded sound will be stronger at the coincidences of the pulses, and fainter when they bisect each other. This reinforcement of sound will therefore recur thrice in every second. The frequency of the pulses are in the ratio of a comma, or 81 : 80. Therefore this constitutes an *unison imperfect by a comma*. If therefore any circumstance should require that these two pulses should form an unison imperfect by a comma, we have only to alter one of the pipes, till the two, when sounded together, beat thrice in a second. Nothing can be plainer than this. Now let us suppose a third pipe tuned an exact fifth to the first of these two. There will be no beating observable; because the recurrence of coincident pulses is so rapid as to appear a continued sound. They recur at every second vibration of the bass, or 120 times in a second. But now, instead of sounding the third pipe along with the first, let it sound along with the second. Dr Smith demonstrates, that they will beat in the same manner as the unisons did, but thrice as often, or nine times in a second. When therefore the fifth C *g* beats nine times in a second, we know that it is too sharp or too flat (very nearly) by a comma.

41
Dr Smith applies them to the science and practice of music with great effect.

Dr Smith shews, in like manner, what number of beats are made in any given time by any concord, imperfect or tempered, in any assigned degree. We humbly think that the most inattentive person must be sensible of the very great value of this discovery. We are obliged to call it *his* discovery. Mersennus, indeed, had taken particular notice of this undulation of imperfect consonances, and had offered conjectures as to their cause; conjectures not unworthy of his great ingenuity. Mr Sauveur also takes a still more particular notice of this phenomenon *, and makes a most ingenious use of it for the solution of a very important musical problem; namely, to determine the precise number of pulses which produce any given note of the gamut. His method is indeed operose and delicate, even as simplified and improved by Dr Smith. The following may be substituted for it, founded on the mechanism of sounding cords. Let a violin, guitar, or any such instrument, be fixed up against a wall, with the finger-board downward, and in such a manner, that a violin string, strained by a weight, may press on the bridge, but hang free of the lower end of the finger board. Let another string be strained by one of the tuning pins till it be in unison with some note (suppose C) of the harpsichord. Then hang weights on the other string, till, upon drawing the bow across both strings, at a small distance below the bridge, they are perfect unisons, without the smallest beating or undulation, and taking care that the pressure of the bow on that string which is tuned by the pin be so moderate as not to affect its tension sensibly. Note exactly the weight that is now appended to it. Now increase this weight in the proportion of the square of 80 to the square of 81; that is, add to it its 40th part very nearly. Now draw the bow again across the strings with the same caution as before. The sounds will now beat remarkably; for the vibrations of the loaded string are now accelerated in the proportion of 80 to 81. Count the number of undulations made in some small number (suppose 10) of seconds. This will give the number of beats in a second; 80 times this number are the single pulses of the lowest sound; and 81 times the same number gives the pulses of the highest of these imperfect unisons.

Pulses of [illegible] = 240.

* Mem. Acad. Par. 17[illegible], 1702, 17[illegible], and 171[illegible]

If this experiment be tried for the C in the middle of our harpsichords, it will be found to contain 240 pulses very nearly; for the strings will beat thrice in a second. The beats are best counted by means of a little ball hung to a thread, and made to keep time with the beats.

42
They afford exact measures of the temperament of concords.

Here, then, is a phenomenon of the most easy observation, and requiring no skill in music, by which the pitch of any sound, and the imperfection of any concord, may be discovered with the utmost precision; and by this method may concordant sounds be produced, which are absolutely perfect in their harmony, or having any degree of imperfection or temperament that we please. An instrument may generally be tuned to perfect harmony, in some of its notes, without any dif-

ficulty,

Temperament of the Scale of Music.

ficulty, as we see done by every blind Crouder. But if a certain determinate degree of imperfection, different perhaps in the different concords, be necessary for the proper performance of musical compositions on instruments of fixed sounds, such as those of the organ or harpsichord kind, we do not see how it can be disputed, that Dr Smith's theory of the beating of imperfect consonances is one of the most important discoveries, both for the practice and the science of music, that have been offered to the public. We are inclined to consider it as the most important that has been made since the days of Galileo. The only rivals are Dr Brook Taylor's mechanical demonstration of the vibrations of an elastic cord, and its companion, and of the undulations of the air in an organ pipe, and the beautiful investigations of Daniel Bernoulli of the harmonic sounds which frequently accompany the fundamental note. The musical theory of Rameau we consider as a mere whim, not founded in any natural law; and the theory of the grave harmonics by Tartini or Romieu is included in Dr Smith's theory of the beating of imperfect consonances. This theory enables us to execute any harmonic system of temperament with precision, and certainty, and ease, and to decide on its merit when done.

We are therefore surprised to see this work of Dr Smith greatly undervalued, by a most ingenious gentleman in the Philosophical Transactions for 1800, and called a large and obscure volume, which leaves the matter just as it was, and its results useless and impracticable. We are sorry to see this; because we have great expectations from the future labours of this gentleman in the field of harmonics, and his late work is rich in refined and valuable matter. We presume humbly to recommend to him attention to his own admonitions to a very young and ingenious gentleman, who, he thinks, proceeded too far in animadverting on the writings of Newton, Barrow, and other eminent mathematicians. We also beg his leave to observe, that Dr Smith's application of his theory may be very erroneous (we do not say that it is perfect), in consequence of his notion of the proportional effects produced on the general harmony by equal temperaments of the different concords. But the theory is untouched by this improper use, and stands as firmly as any proposition in Euclid's Elements. We are bound to add to these remarks, that we have oftener than once heard music performed on the harpsichord described in the second edition of Dr Smith's Harmonics, both before it was sent home by the maker (the first in his profession), and afterwards by the author himself, who was a very pleasing performer, and we thought its harmony the finest we ever heard. Mr Watt, the celebrated engineer, and not less eminent philosopher, built a handsome organ for a public society, and, without the least ear or relish for music, tuned three octaves of the open diapason by one of Dr Smith's tables of beats, with the help of a variable pendulum. Signior Doria, leader of the Edinburgh concert, tried it in presence of the writer of this article, and said, "Bellissima—sopra modo bellissima!" Signior Doria attempted to sing along with it, but would not continue, declaring it impossible, because the organ was ill tuned. The truth was, that, on the major key of E♭, the tuning was exceedingly different from what he was accustomed to, and he would not try another key. We mention this particular, to shew how accurately Mr Watt had been able to execute the temperament he intended.

This theory is valuable, therefore, by giving us the management of a phenomenon intimately connected with harmony, and affording us precise and practicable measures of all deviations from it. It bids fair, for this reason, to give us a method of executing any system of temperament which we may find reason to prefer. But we have another ground of estimation of this theory. By its assistance, we are able to ascertain with certainty and precision the true untempered scale of music, which eluded all the attempts of the ingenious Greeks; and we determine it in a way suited to the favourite music of modern times, of which almost all the excellencies and pleasures are derived from harmony. We do not say that this *total* innovation in the principle of musical pleasure is unexceptionable; we rather think it very defective, believing that the thrilling pleasures of music depend more upon the melody or air. We appeal even to instructed musicians, whether the heart and affections are not more affected *(and with much more distinct variety of emotion)* by a fine melody, supported, but not observed, by harmonies judiciously chosen? It appears to us that the effect of harmony, always filled up, is more uniformly the same, and less touching to the soul, than some simple air sung or played by a performer of sensibility and powers of utterance. We do not wonder, then, that the ingenious Greeks deduced all their rules from this department of music, nor at their being so satisfied with the pleasures which it yielded, that they were not solicitous of the additional support of harmony. We see that melody has suffered by the change in every country. There is no Scotchman, Irishman, Pole, or Russian, who does not lament that the skill in composing heart-touching airs is degenerated in his respective nation; and all admire the productions of their muse of "the days that are past." They are "pleasant and mournful to the soul."

43 And accurate methods of temperament.

But we still prefer the harmonical method of forming the scale, on account of its precision and facility: and we prefer the theory of beats, *because it also gives us the most satisfactory scale of melody;* and this, not by repeated corrections and recorrections, but by a direct process. By a table of beats, every note may be fixed at once, and we have no occasion to return to it and try new combinations; for the beatings of the different concords to one bass being once determined, every beating of any one note with any other is also fixed.

44 Fundamental experiment.

We therefore request the reader's patient attention to the experiment which we have now to propose. This experiment is best made with two organ pipes equally voiced, and pitched to the note C in the middle of our harpsichords. Let one of them at least be a stopped pipe, its piston being made extremely accurate, and at the same time easily moved along the pipe. Let the shank of it be divided into 240 equal parts. The advantage of this form of the experiment is, that the sounds can be continued, with perfect uniformity, for any length of time, if the bellows be properly constructed. In default of this apparatus, the experiment may be made with two harpsichord wires in perfect unison, and touched by a wheel rubbed with rosin instead of a bow, in the way the sounds of the vielle or hurdygurdy are produced. This contrivance also will continue the sounds uniformly at pleasure. A scale of 240 parts must

Tempera-ment of the Scale of Music.

must be adapted to one string, and numbered from that end of the string where the wheel or bow is applied to it. Great care must be taken that the shifting of the moveable bridge do not alter the strain on the wire. We may even do pretty well with a bow in place of the wheel; but the sound cannot be long held on in any pitch. In describing the phenomena, we shall rather abide by the string, because the numbers of the scale, or length of the sounding part of the wire, correspond, in fact, much more exactly with the sounds. The deviations of the scale of the pipe do not in the least affect the conclusions we mean to draw, but would require to be mentioned in every instance, which would greatly complicate the process.

Having brought the two open strings into perfect unison, so that no beating whatever is observed in the consonance, slide the moveable bridge slowly along the string while the wheel is turning, beginning the motion from the end most remote from the bow. All the notes of the octave, and all kinds of concords and discords, will be heard; each of the concords being preceded and followed by a ruffling beating, and that succeeded by a grating discord. After this general view of the whole, let the particular harmonious stations of the bridge be more carefully examined as follows.

45 Determination of the octave, and character of concord.

I. Shift the moveable bridge to the division 120. If it has been exactly placed, we shall hear a perfect octave without any beating. It is, however, seldom so exactly set, and we generally hear some beating. By gently shifting the bridge to either side, this beating becomes more or less rapid; and when we have found in which direction the bridge must be moved, we can then slide it along till the beating cease entirely, and the sounds coalesce into one sound. We can scarcely hear the treble or octave note as distinguishable from the bass or fundamental afforded by the other string. If the notes are duly proportioned in loudness, we cannot hear the two as distinct sounds, but a note seemingly the same with the fundamental, only more brilliant. (*N B.* It would be a great improvement of the apparatus to have a micrometer screw for producing those small motions of the bridge.)

Having thus produced a fine octave, we can now perceive that, as we continue to shift the bridge from its proper place, in either direction, the beating becomes more and more rapid, changes to a violent rattling flutter, and then degenerates into a most disagreeable jar. This phenomenon is observed in the deviation of every concord whatever from perfect harmony, and must be carefully kept in remembrance.

46 Harmony more strict than melody.

Before we quit this concord, the octave, produced by the bisection of the pipe or string, we must observe, that, with respect to ourselves, the octave $c\bar{c}$ must beat almost twice in a second, before we can observe clearly any mis-tune in it, by sounding the notes in succession, or as steps in the scale of melody. We never knew any ear so nice as to discover a mis-tuning when it beats but once in three seconds. We think ourselves intitled therefore to say, that we are insensible of a temperament in melody amounting to one third of a comma; and we never knew a person sensible of a temperament half this bulk.

When the imperfection of the octave is clearly sensible by sounding the notes in succession, it is extremely disagreeable, feeling like a struggle or endeavour to attain a certain note, and a failure in the attempt. This seems owing to the familiar similarity of octaves, in the habitual talking and singing of men and women together. But when the notes are sounded together, although we are not much more sensible of the imperfection of the harmony directly, as a failure in the sweetness of the concord, we are very sensible of this phenomenon of beating; and any person who can distinguish a weak sound from a stronger one, can easily perceive, in this indirect manner, any fraction of a comma, however minute. This makes the tuning by harmony much more exact than by melody alone. It is also much more accommodated to the genius of modern music. The ancients had favourite passages, which were frequently introduced into their airs, and they were solicitous to have these in good tune. It appears from passages in the writings of Galen, that different performers excelled chiefly in their skill in making those occasional temperaments which their music required. Our music is much more strict, by reason of our harmonic accompanyments, which are an abominable noise when mis-tuned in a degree, which would have passed with the ancients for very good melody. Aristoxenus says, that the ear cannot discover the error of a comma. This would now be intolerable.

47 It gives the best scale for melody.

But another advantage attends our method. We obtain, by its assistance, the most perfect scale of melody; perfect in a degree attainable only by chance by the Greeks. This is now to be our business to unfold.

48 Determination of the 5th.

II. Set the moveable bridge at 158, and sound the two strings. They will beat very disagreeably, being plainly out of tune. Slide it gradually toward 160, and the beats will grow slower and slower; will change to a gentle and not unpleasant undulation; and at last, when the bridge is at 160, will vanish entirely, and the two sounds will coalesce into one sweet concord, in which neither of the component sounds can be distinguished. If the sound given by the short string be now examined as a step in the scale of melody, it will be found a fifth to the sound of the long string or fundamental note, perfectly satisfactory to the nicest ear. Thus one step of the scale has been ascertained.

III. Slide the bridge slowly along the string. The beating will recommence, will become a flutter, and then a jarring noise; and will again change to an angry flutter, beating about eight times in a second, when the bridge stands at 169 nearly. Pushing it still on, but very slowly, the flutter will become an indistinct jarring noise; which, by continuing the motion, will again become a flutter, or beat about six in the second. The bridge is now about 171.

49 Determination of the 4th.

IV Still continuing the motion, the flutter becomes a jarring noise, which continues till the bridge is near to 180, when the rapid flutter will again be heard. This will become slower and slower as we approach to 180; and when the bridge reaches that point, all beating vanishes, and we have a soft and agreeable concord, but far inferior to the former concord in that cheering sweetness which characterises the fifth. When this note is compared with that of the fundamental string as a step in the scale of melody, it is found to correspond to the note *fa*, or the fourth step in the scale, and in that employment to give complete satisfaction to the ear.

V. Still advancing the moveable bridge toward the

Temperament of the Scale of Music. nut, we shall hear the beatings return again; and after fluttering and degenerating to a jarring noise, by a very small motion of the bridge, they will again be heard, will grow slower, accompanied with a sort of angry expression, and will cease entirely when the bridge reaches

50 Determination of the IIId. the 192d division of our scale. Here we have another concord of very peculiar character, being remarkably enlivening and gay. This sound gives perfect satisfaction to the ear, if employed as the third step in the scale of melody, being the note *mi* of that series, at least in all gay or cheerful airs.

51. VI. As we move the bridge from 192 to 200, we hear again the same beatings, which, in the immediate vicinity to 192, have a peevish fretful expression, instead of the angry waspish expression before mentioned. When the bridge has passed that situation which produces only grating discordance, we hear the beatings again, and they become slower, and cease altogether when the bridge arrives at 200. Here we have another consonance, which must be called a *concord*, because it is rather agreeable than otherwise, but strongly marked by a mournful melancholy in the expression. In the scale of melody, it forms the third step in those airs which express lamentation or grief. It is called the *minor third*, to distinguish it from the last enlivening concord, which, being a larger interval, is called the *major third*.

52 Determination of the 3d. It is well known, that these two thirds give the distinguishing characters to the only two modes of melodious composition that are admitted into modern music. The series containing the major third is called the *major*, and that containing the minor third is called the *minor mode*. It is worthy of remark, that the fanatical preachers, in their conventicles and field sermons, affect this mode in their harangues, which are often distinctly musical, modulating entirely by musical intervals, and keeping the whole of their chaunt in subordination to a fundamental or key note. This is not unnatural, when we consider the general scope of their discourses, namely, to inspire melancholy and humiliating thoughts, awakening sorrow, and the like. It is not so easy to account for the usual whine of a beggar, who generally craves charity in the major third. This is the case, at least, in the northern parts of this island.

53. If we continue to shift the bridge still nearer to the end of the string, we shall hear nothing but a succession of vile discordant noises, somewhat less offensive when the bridge is about the divisions 213 and 216, but even there very unpleasant.

54 Determination of the 6th. VII. Let us therefore change our manner of proceeding a little, and again place the bridge at 160, which will give us the pleasing concord of the fifth. Instead of pushing it from that place toward the nut, let it be moved toward the wheel or bow. Without repeating what we have said of the reappearance of the beatings, their acceleration, and their degenerating into a jarring discord, to be afterwards succeeded by another beating, &c. &c. we shall only observe, that when we place the bridge at 150, we have no beatings, and we hear a consonance, which is in a slight degree pleasant, and may therefore be called a *concord*. It has the other marks of a concord which we have been making so much use of; for the beatings recommence when we shift the bridge to either side of 150. This note makes the sixth step in the descending scale of mournful melody; that is, when we are passing from the acute to the graver notes, with the intention of putting an emphasis on the third and the fundamental. Although not eminent as a concord with the fundamental alone, it has a most pleasing effect when listened to in subordination to the whole series, or when sounded along with other proper accompanyments of the fundamental.

VIII. Placing the bridge at 144, we obtain another very pleasing concord, differing in its expression from any of the foregoing. We find it difficult to express its character. It is greatly inferior to the fifth in sweetness, and to the major third in gaiety, but seems to possess, in a lower degree, both of those qualities. In the scale of cheerful melody, it is the sixth note, which we have distinguished by the syllable *la*. It is also used even in mournful melody, when we are ascending, with the intention of closing with the octave. 55 Determination of the VIth.

In shifting the bridge from 144 to 120, we obtain nothing but discordant, or at least disagreeable consonances. And, lastly, if we move the bridge beyond 120, to divisions which are respectively the halves of those numbers which produced the concords already treated of, we obtain the same steps in the scale of the upper octave. Thus if the bridge be at 80, we have the fifth to the octave note, or twelfth to the fundamental. If it be at 60, we obtain the double octave, &c. &c. &c. 56 Scale of the upper octave.

We have perhaps been rash in affixing certain moral or sentimental characters to certain concords; for we have seen instances of persons who gave them different denominations; but these were never contradictory to ours, but always expressed some sentiment allied to that which we have assigned. We never met with an instance of a person capable of a little discriminating reflection, who did not acknowledge a manifest sentimental distinction among the different concords which could not be confounded. We doubt not but that the Greeks, a people of exquisite sensibility to all the beauties of taste and sentiment, paid much attention to these characters, and availed themselves of them in their compositions. We do not think it at all unlikely, that greater effects have been produced by their music, which was studied with this express view, than have ever been produced by the modern music, with all the addition of harmony. We have allowed too great a share of our attention to mere harmony. Our great authors are much less solicitous to compose an enchanting air, than to construct a full score of rich and well conducted harmony. We do not profess to be nice judges in musical composition, but we may tell what we ourselves experience. We find our minds worked up by a continuance of fine harmony into a *general* sensibility; into a frame of mind which would prepare and fit us for receiving strong impressions of moral sentiment, if these were distinctly made. But we have seldom felt any distinct emotions excited by mere instrumental music. And when the harmonies have been merely to support the performance of a voice, the words have been either so frittered by musical divisions, as to become in some measure ludicrous—or have been so indistinct, and made so trifling a part of the music, that there was nothing done to give a particular shape to the moral impression on our mind. We have generally been strongly affected by some of the anthems which were in vogue in former times; and we think that we perceived the cause of 57 Characters of the different concords.

Temperament of the Scale of Music.

of this difference. There was a great simplicity in the voice parts: the syllables were not drawled out into long musical phrases, but pronounced nearly according to their proper quantities; so that the sentiment of the speaker was expressed with all the force of good declamation, and the harmony of the accompanyment then strengthened the appropriate effect of the melody. We mean not to offer these observations as of much authority, but merely to mention some facts, and to assign what we felt to be their causes, in order to promote, in some degree, however insignificant, the cultivation of musical science. With this view, we venture to say, that some of the best compositions of Knapp of York *uniformly* affect us more than the more admired anthems of Bird and Tallis. A cadence, which Knapp gives almost entirely to the melody, is laboured by Bird or Tallis with all the rules of art; and you have its characters of perfect or imperfect, full or disappointed, cadences, and such an apparatus of preparation and resolution of discords, that you foresee it at the distance of several bars, and then the part assigned to the voice seems a very trifle, and merely to fill up a blank in the harmony. Such compositions smell of the lamp, and fail of their purpose, that of charming the *learned* ear. But enough of this digression.

58. Thus have we found a natural relation between certain sounds strongly marked by very precise characters. The concordance of sound is marked by the absence of all undulation, and the deviations from this harmony are shewn to be measurable by the frequency of those undulations. We have also found, that the notes, which are thus harmonious along with the fundamental, are steps in the scale of natural music (for we must acknowledge melody to be the primitive music, dictated by nature). We have got the notes *do—mi*, *fa*, *sol*, *la—do*, ascertained in a way that can no longer be mistaken.

59. Relations belonging to the concords, &c.

Let us now examine what physical or mechanical relations these sounds stand into each other. Our monochord gives us the lengths of the strings; and the discovery of Galileo shews us, that these are also the durations of the aëreal pulses which produce the sensations of musical notes. Their ratios may therefore be truly called the ratios of the sounds. Now we see that the strings which produce the sounds *do sol* are 240 and 160. These are in the ratio of 3 to 2. In this manner we may state all the ratios observed in our experiment, *viz.*

Do : *mi* have the ratio of	240 to 192, or of	5 to 4
Do : *fa*	240 : 180	4 : 3
Do : *sol*	240 : 160	3 : 2
Do : *la*	240 : 144	5 : 3
Mi : *sol*	192 : 160	6 : 5, = *do* : *mi*^{b}
Fa : *sol*	180 : 160	9 : 8
Sol : *la*	160 : 144	10 : 9
Mi : *fa*	192 : 180	16 : 15

Here we get the sight of all the ratios which the ingenious and unwearied speculations of the Greek mathematicians enlisted into the service of music, without being able to give a good reason why. The ratio 5 : 4, which their fastidious metaphysicians rejected, and which others wished to introduce from motives of mere necessity to fill up a blank, is pointed out to us by one of the finest concords. The interval between the fourth and the fifth is, *very fortunately*, a step of the scale.

The next step *sol la* is more important. For the ear for melody would have been very well satisfied with an interval equal to *fa sol*, or 9 : 8; but if the moveable bridge be set at the division $142\frac{2}{9}$, corresponding to such a step, we should have a very offensive fluttering. It is reasonable therefore to conclude, *from analogy*, that the interval *sol la* does not correspond to the ratio 9 : 8; and that 10 : 9, which is, at least, equally satisfactory to the ear, is the proper step, even in the scale of melody. If we consider what may be called the scale of harmony, there is no room left for doubt. To enjoy the greatest possible pleasure of harmony, we must not only take each note as it is related to the fundamental, but also as it is related to other notes of the scale. It may chance to be convenient to assume, for the fundamental of our occasional scale of modulation, the string of the lyre which is tuned as *fa* to its proper fundamental; or it may increase the harmony (and we know that it does) if we accompany the note *do* with both of the notes *fa* and *la*. To have the fine concord of the major third, it is necessary that the interval *fa la* be equivalent to the ratio 5 : 4. Now *fa* is 180, and 5 : 4 = 180 : 144. Therefore, by making the step *sol la* equal to 9 : 8, we should lose this agreeable concord, and get discord in its place.

Temperament of the Scale of Music.

60. Observations on the step *sol la*.

And thus is evinced, in opposition to Aristoxenus, the propriety of having both a major and a minor tone; the first expressed by 9 : 8, and the last by 10 : 9. The difference between these steps is the ratio 81 : 80, called a comma by the Greek theorists.

61. Determination of the VIIth.

We still want two steps of the scale, and two sounds or notes corresponding to them, namely *re* and *si*; and we wish to establish them on the same authority with the rest. We see that this cannot be done by a concordance with the fundamental *do*. The ear sufficiently informs us that the steps *do re* and *la si* must be tones, and not semitones, like *mi fa*. The sensible similarity of the two tetrachords *do re mi fa* and *sol la si do*, also teaches us that the step *si do* should be a semitone like *mi fa*. This seems to be all that mere melody can teach us. But we have little information whether we shall make *la si* a major or a minor tone. If we copy the tetrachord *do re mi fa* exactly, we shall make the step *si do* like *mi fa*, and equivalent to the ratio 16 : 15. This requires the moveable bridge to be placed at 128. The sound produced by this division is perfectly satisfactory to the ear as a step of the scale of melody. Moreover, our satisfaction is not confined to the comparison of it with the note *do*, into which we slide by this gentle step. It makes agreeable melody when used as the third to the note *sol*. If we examine it mathematically, we find it a perfect major third to *sol*; for *sol* requires the 160th division. Now 160 : 128 = 5 : 4, which is the ratio of the pulses of a major third. All these reasons seem enough to make us adopt this determination of the note *si*.

62. Determination of the IId.

It remains to consider how we shall divide the interval *do—mi*. It is a perfect major third. So is *fa la*, and so is *sol si*. But in the first of these two, we have seen that it must be composed of a major tone with a minor tone above it; and in the second we have a minor tone followed by a major tone above. We are left uncertain therefore whether *do re* shall resemble *fa la* or *sol si* in the position of its two parts. Aristoxenus and his followers declared the ear to be equally pleased with both. Ptolemy's *Systema Diatonicum Intensum* makes *do re* a major tone, and other systems make it a minor. E-

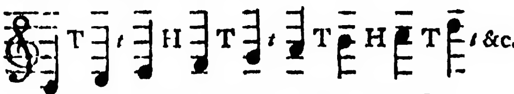
Temperament of the Scale of Music.

ven in modern times it has been considered as uncertain; and the only reason which we have to offer for a preference of the major tone for the first step is, that, so far as we can judge by our own feelings, the sounds in the relation of 9 : 8 are less discordant than sounds in the relation of 10 : 9, and because all the other steps have been determined by means of concords with the key. We refer, for a more particular examination of the principles on which these arrangements are valued, to *Dr Smith's Harmonics*, Prop. I. where he shews how one is preferable to another, in proportion as it affords a greater number of perfect concords among the neighbouring notes, which is the favourite object in all modern music. Upon this principle our arrangement is by far the best, because it admits five more concords in the octave than the other. But we have considered the subject in a different manner, merely to avail ourselves of the phenomenon by which all the steps, except one, seem to be naturally ascertained, and by which the connection between harmony and melody seems to be pointed out to us.

63.

It will be convenient to represent the tones major and minor and the hemitone, by the symbols T, *t*, and H. Also to mark the notes by the Roman numerals, or by cyphers, according as they are the extremes of major or minor intervals. By this notation the octave may be represented thus:

C D E F G A B *c* *d* *e*



$\frac{8}{9}$ $\frac{9}{10}$ $\frac{15}{16}$ $\frac{8}{9}$ $\frac{9}{10}$ $\frac{8}{9}$ $\frac{15}{16}$ $\frac{8}{9}$ &c.

K II III 4 V VI VII VIII IX X &c.

The reader will remark, that the primary divisions which we assigned to the representation of an octave in fig. 1. by the circumference of a circle, are in conformity to this Ptolemaic partition of the octave. He will also be sensible, that the division into five equal mean tones and two equal hemitones, which is expressed by the dotted lines, agreeing with the Ptolemaic division only at C and E, is effected by bisecting the arch CE; and therefore the deviation of the sound substituted for the Ptolemaic D is half the difference of CD and DE, that is, half a comma. The deviations therefore at F, G, A, and B, are each a quarter of a comma.

Logarithmic measure of the musical intervals.

It is well known, that if the logarithm of the length of one string be subtracted from that of another, the difference is a measure of the ratio between them. Therefore 30103 is the measure of the musical interval called the octave, and then the measures of the

Comma	540 or	54
Hemitone	2803	280
Minor tone	4576	458
Major tone	5115	512
3d	7918	792
IIId	9691	969
4th	12494	1249
Vth	17609	1761
6th	20412	2041
VIth	22185	2219
VIIth	27300	2730
VIIIth	30103	3010

This is a very convenient circumstance. If we take only the four first figures as integers, and make the octave consist of 3010 parts, we have a scale more exact than the nicest harmony requires. The circumference of a circle may be so divided into 301 degrees, and the moveable circle have a nonius, subdividing each into 10. Or it may be divided into 55,8 degrees, each of which will be a comma. Either of these divisions will make it a most convenient instrument for expeditiously examining all temperaments of the scale that can be proposed. Or a straight line may be so divided, and repeated thrice. Then a sliding ruler, divided in the same manner, and applied to it, will answer the same purpose. We shall see many useful employments of these instruments by and by.

Having thus endeavoured to communicate some plain notion of the formation and singular nature of that gradation of sounds which produces all the pleasures of music, and of the manner of obtaining the steps of this gradation with certainty and precision, we proceed to consider how those musical passages may be performed on such keyed instruments as the organs and harpsichords, as they are now constructed. These instruments have twelve sounds and intervals in every octave, in order that an air may be performed in any pitch; that is, taking any one of the sounds as a key note. It is plain that this cannot be done with accuracy; for we have now seen that the interval *mi fa* is bigger than half of *do re* or *re mi*, &c. and therefore the intercalary sound formerly mentioned to be inserted between C and D, D and E, &c. will not do indiscriminately for the sharp of the sound below and the flat of the sound above it. When the tones are reduced to a mean size, the ear is scarcely sensible of the change in melody, and the harmony of the fifths and fourths is not greatly hurt. But when the half notes are inserted, and employed to make up harmonious intervals, as recommended by Zarlino, the harmony is very coarse indeed.

65 Why temperament necessary.

But we must make the reader sensible of the necessity of some temperament, even independent of those artificial notes. Therefore

Let the scholar tune upwards the four Vths $c\,g$, $g\,\bar{d}$, $\bar{d}\,\bar{a}$, $\bar{a}\,\bar{\bar{e}}$, all perfect, admitting no beating whatever. This is easily done, either with the organ or the wheel monochord already described. Then tune downwards the perfect octaves $\bar{\bar{e}}\,\bar{e}$, $\bar{e}\,e$. Now examine the IIId $c\,e$ which results from this process. If the instrument be of the pitch hitherto supposed (c making 240 pulses in a second), this IIId will be heard beating 15 times in a second, which is a discordance altogether intolerable, the note e being too sharp in the ratio of 81 to 80, which makes a comma. It is easily found, by calculation, that e makes $303\frac{3}{4}$ pulses, instead of 300, required for the IIId to c.

N. B. It may not be amiss to inform our readers, that if any concord, whose perfect ratio is $\frac{m}{n}$ (m being the greatest term of the smallest integers expressing that ratio), be tempered sharp by the fraction $\frac{p}{q}$ of a comma, and if M and N be the pulses made by the acute and grave notes of the concord during any number of seconds, the number b of beats made in the same time by this concord will be $= \frac{2\,q\,m\,N}{161\,p-q}$, or $\frac{2\,q\,n\,M}{161\,p+q}$;

and

Temperament of the Scale of Music.

and if it be tempered flat, then $b = \frac{2qmN}{161\overline{p+q}}$, or $\frac{2qnM}{161\overline{p+q}}$ (*Smith's Harm.* 2d edit. p. 82, &c.)

66. It is impossible, therefore, to have perfect Vths and perfect IIIds at the same time. And it will be found, that the 3d $e\,g$ resulting from this process, and the VIth $c\,\overline{a}$, are still more discordant, rattling at an intolerable rate. Now the major and minor thirds, alternately succeeding each other, form the greatest part of our harmonies; and the VIth is also a very frequent accompanyment. It is necessary therefore to sacrifice somewhat of the perfect harmony of the Vths, in order that we may not be disgusted with the discord of those other harmonies: and it is this mutual accommodation, and not the changes made necessary by the introduction of intercalary notes, which is properly called TEMPERAMENT. It will greatly assist us in understanding the effects of the temperaments of the different concords, if we examine all the divisions of the circular representation of the octave and musical scale given in fig. 1. by placing the index of the moveable circle on that note of the outer circle for which we want the proper harmonics, or accompanyments, which are either the IIId and Vth, or the 4th and VIth. We shall thus learn, in the *first* place, the deviations of the different perfect notes of the scale from the notes required for this new fundamental; and we must then study what effect the same temperament produces on the agreeableness of the harmony of different concords having the same bass or the same treble, taking it for granted that the hurt to the harmony of any individual concord is proportional to its temperament.

67 How this may be obtained by the beats.

It is in this delicate department of musical science that we think the great merit of Dr Smith's work consists. We see that the deviation from perfect harmony is always accompanied with beats, and increases when they increase in frequency—whether it increases in the same proportion may be a question. We think that Dr Smith's determination of the equality of imperfect harmony in his 13th proposition includes every mathematical or physical circumstance that appears to have any concern in it. What relates immediately to our sensations is, as yet, an impenetrable secret. The theory of beats, as delivered by this author, affords very easy, though sometimes tedious, methods of measuring and of ensuring all the varieties which can obtain in the beating of imperfect consonances. It appears to us therefore very unjust to say, with the late writer in the Philosophical Transactions, that this obscure volume has left the matter where it found it. The author has given us *effective* principles, although he may have been mistaken in the application; which however we are far from affirming. Our limits will not allow us to give any account of that theory; and indeed our chief aim in the present article is to give a method of temperament which requires no scientific knowledge of the subject. But we could not think of losing the opportunity of communicating, by the way, to unlearned persons, some more distinct notions of the scale of musical sounds, and of its foundation in nature, than scholars usually receive from the greater number of mere music masters. The acknowledged connection of the musical ratios with the pleasures of harmony and melody, has (we hope) been employed in an easy and not obscure manner; and the phenomena which we have faithfully narrated shew plainly that, by diminishing the rattling undulations of tempered concords, we are certain of improving the harmony of our instruments. We shall proceed therefore on this principle for the use of the mere performer, but at the same time introducing some very simple deductions from Smith's theory, for which we expect the thanks of all such readers as wish to see a little of the reasons on which they are to proceed.

68 Method in practice.

The experiment, of which we have just now given an account, shews that four consecutive fifths compose a greater interval than two octaves and a major third. Yet, in the construction of our musical instruments of fixed sounds, they must be considered as of equal extent; since we have 7 half intervals in the Vth, and 12 in the octave, and four in the IIId, four Vths contain 28, and two octaves contain 24; and these, with the four which compose a IIId, make also 28. It is plain, therefore, that whatever we do with the IIIds, we must lessen the Vths. If therefore we keep the IIId perfect, we must lessen each of the Vths by $\frac{1}{4}$th of a comma; for we learned, by the beating of the imperfect IIId $c\,e$, that the whole excess of the four Vths was a comma. Therefore the Vth $c\,g$ must be flattened $\frac{1}{4}$th of a comma. But how is this to be done with accuracy? Recollect the formula given a little ago, where the number of beats b in any number of seconds is $= \frac{2qmN}{161 \times \overline{p+q}}$. In the present case $q = 1$, $m = 3$, $N = 240$ per second, and $p = 4$. Therefore the formula is $= \frac{2 \times 3 \times 240}{161 \times \overline{4+1}} = \frac{1440}{645} = 2{,}25$ in a second, or 9 beats in four seconds very nearly.

In like manner, the next Vth $g\,\overline{d}$ must be flattened $\frac{1}{4}$th of a comma, by making it beat half as fast again, or $13\frac{1}{2}$ beats in four seconds (because in this Vth $N = 360$). But as this beating is rather too quick to be easily counted, it will be better to tune downwards the perfect octave g G, which will reduce N to 180 for the Vth G d. This will give us 1,68 per second, or 10 beats in 6 seconds very nearly.

There is another way of avoiding the employment of too quick beats. Instead of tuning the octave g G, make c G beat as often as $c\,g$. This is even more exactly an octave to g than can be estimated by a good ear. Dr Smith has demonstrated, that when a note makes a minor concord with another note below it, and therefore a major concord with the octave to that note, it beats equally with both; but if the major concord be below, it beats twice as fast with the octave above. Now, in the present case, $c\,g$ is a Vth, and c G a 4th. For the same reason $c\,f$ would beat twice as fast as c F.

In the next place, the Vth $\overline{d}\,\overline{a}$ must be made to beat flat 15 times in 6 seconds.

In like manner, instead of tuning upward the Vth $\overline{a}\,\overline{e}$, tune downward the octave $\overline{a}\,a$, and then tune upward the Vth $a\,e$, and flatten it till it beat 15 times in 8 seconds.

If we take 15 seconds for the common period of all these beats, we shall have

The

Temperament of the Scale of Music.

The beats of $cg = 34$.
$Gd = 25$.
$da = 37\frac{1}{2}$.
$ae = 28$.

69. We shall now find ce to be a fine IIId, without any sensible beating; and then we proceed in the same way, always tuning upward a perfect Vth; and when this would lead us too high, and therefore produce too quick beating, we should tune downward an octave. Do this till we reach b ✗, which should be the same with $\bar{c}$, or a perfect octave above c. This will be a full proof of our accurate performance. But the best process of tuning is to stop when we get to g ✗. Then we tune Vths downward from c, and octaves upward when the Vths would lead us too low. Thus we get c F, Ff, $f b^b$, $b^b \bar{b}^b$, $\bar{b}^b e^b$, and thus complete the tuning of an octave. We take this method, instead of proceeding upwards to b ✗; because those notes marked sharp or flat are, when tuned in this way, in the best relation to those with which they are most frequently used as IIIds.

70 Use of a variable pendulum. This process of temperament will be greatly expedited by employing a little pendulum, made of a ball of about two ounces weight, sliding on a light deal rod, having at one end a pin hole through it. To prepare this rod, hang it up on a pin stuck into the wainscoting, and slide the ball downward, till it makes 20 vibrations in 15″, by comparing it with a house clock. In this condition mark the rod at the upper edge of the ball. In like manner, adjust it for 24, 28, 32, 36, 40, 44, 48, vibrations, making marks for each, and dividing the spaces between them by the eye, noticing their gradual diminution. Then, having calculated the beats of the different Vths, set the ball at the mark suited to the particular concord, and temper the sound till the beats keep pace exactly with the pendulum.

71 Absolute number of pulses how known. But, previous to all this, we must know the number of pulses made in a second by the C of our instrument. For this purpose we must learn the pulses of our tuning fork. To learn this, a harpsichord wire must be stretched by a weight till it be unison or octave below our fork: then, by adding $\frac{1}{40}$th of the weight to what is now appended, it will be tempered by a comma, and will beat, when it is sounded along with the fork; and we must multiply the beats by 80: The product is the number of pulses required. And hence we calculate the pulses of the C of our instrument when it is tuned in perfect concord with the fork.

The usual concert pitch and the tuning forks are so nearly consonant to 240 pulses for C, that this process is scarcely necessary, a quarter of a tone never occasioning the change of an entire beat in any of our numbers.

72 System of temperament with perfect IIId. The intelligent reader cannot but observe, that this system of tuning with perfect IIIds, which is preferred to all others by many great masters, is the one represented by our circular figure of the octave. The IIId is there perfect, and the Vth CG is deficient by a quarter of a comma. We cannot here omit taking notice of a most valuable observation of Dr Smith's on this temperament, and, in general, on any division of the octave into mean tones and equal limmas.

73 Proportional variation of temperament. The octave being made up of five mean tones and two limmas, it is plain that, by enlarging the tones, we diminish the limmas, and that the increment of the tone is two fifths of the contemporaneous diminution of the limma. If, therefore, we employ the symbol v to express any minute variation of this temperament, and make the increment of a mean tone $= 2v$, the contemporaneous variation which this induces on a limma $= -5v$; and if the tone be diminished by the same quantity $-2v$, the limma will increase by the quantity $5v$. Let us see what are the contemporaneous changes made on all the intervals of the octave when the tone is diminished by $2v$.

1. A Vth is made up of three tones and a limma. Therefore the variation of its temperament is $= -6v + 5v$, or is $= -v$. That is, the Vth is flattened from its former temperament, whatever that may have been, by the quantity $-v$. Consequently the 4th, which is always the complement of the Vth to the octave, has its temperament sharpened by the quantity v.

2. A IId, being a tone distant from the fundamental, has its temperament changed by $-2v$.
Therefore a minor 7th is raised by $2v$.

3. A minor 3d is made up of a tone and a limma: therefore its variation is $= -2v + 5v$, or $= 3v$.
Therefore a major VIth (its complement) loses $-3v$.

4. A maj. IIId, or two tones, has its variation $= -4v$.
Therefore a minor 6th has its variation $= 4v$.

5. A maj. VIIth, the complement of a limma has $-5v$.

6. A tritone, or IVth, must have the variation $= -6v$.
Therefore the false 5th must have . . . $6v$.

74 Geometrical construction founded on this. From this observation, Dr Smith deduces the following simple mathematical construction: In the strait line CE (fig. 2.) take the six equal parts Cg, $g\,d$, $d\,a$, a E, E b, $b\,t$, and draw through the points of division the six parallel lines g G, dD, &c. Let these lines represent so many scales of the octave, so placed that the points C, g, d, &c. may represent the points C, g, d, &c. of the circular scale in fig. 1. where it is cut by the dotted lines representing the system of mean tones and limmas. Then, *1st*, take a certain length dG on the first line, to the right hand of the line CE, to represent a quarter of a comma, G will mark the place of the perfect Vth, while g represents that of the mean or tempered Vth. *2dly*, Set off dD, double of g G, in like manner, to the right hand on the second parallel. This will be the place of the perfect IId to the key note C. *3dly*, Also set off a A, on the third parallel, to the left hand, equal to g G. This will mark the place of A, the VIth to the key note C. *4thly*, Place E on the point e, because, in the system of mean tones represented in fig. 1. the IIIds were kept perfect. *5thly*, Make b B, to the right hand on the fifth line, equal to g G, to mark the place of the perfect VIIth to the key note C. And, *6thly*, make t T, to the right hand on the sixth line, equal to twice g G. This will serve for shewing the contemporaneous temperament of the tritone, or IVth, contained between F and B, as also of its complement, the false 5th in fig. 1.

It is evident that the temperament of all the notes of the octave, according to the above-mentioned system, are properly represented in this figure. The Vth is tempered flat by the quarter comma Gg; the IId is tempered flat by the half comma Dd; the VIth is tempered sharp by a quarter comma Aa; the IIId is perfect; the VIIth is flat by a quarter comma Bb; and the 4th is sharp by a quarter comma Gg.

75 The temperer. Now, let any other straight line C t' be drawn from C across these parallels. This will mark, by the intervals

Temperament of the Scale of Music.

vals g' G, d' D, &c. the temperaments of another syſtem of mean tones and limmas. For it is evident, that the contemporaneous variations gg', dd', &c. from the former temperament, are in the juſt proportions to each other; gg' being $= - v$, the variation proper for the Vth, and the oppoſite temperament for its complement or 4th. In like manner, aa' is $= 3v$, the variation competent to the VIth; and E e' is $= 4v$, the proper variation for the IIId.

In like manner, bb' is $= 5v$, the variation of the VIIth and 2d. And, laſtly, tt' is the variation $6v$ of the tritone, and its complement, the falſe fifth.

For all theſe reaſons, any ſtraight line C e' or C e'', drawn from C acroſs the parallels, may juſtly be called the TEMPERER.

76 This is a very uſeful conſtruction: For it is plain, that the ſounds which can be placed in our organs and harpſichords, which have only twelve keys for an octave, muſt approach to a ſyſtem of mean tones. The diviſion of the octave into twelve equal intervals is ſuch a ſyſtem of mean tones exactly. Now, in ſuch ſyſtems, when a line is drawn from C acroſs the parallels, we ſee, at one glance, not only all the temperaments of the notes with the key note, but alſo the temperaments of thoſe concords which the notes employed in full harmony make with each other. Thus, in the harmony of K — III — V, the III and V make a minor 3d with each other; and in the harmony of K — 4 — VI, the 4 and VI make a major 3d with each other. Now the reader will eaſily ſee, that the firſt of theſe concords has its interval diminiſhed on both ſides, when the III is tempered ſharp, but only on one ſide when it is tempered flat. The mathematical reader will alſo eaſily ſee, that the contemporaneous temperament A a' of the VIth is always equal to the ſum g' G and E e', and that A a'' is equal to the difference of g'' G and E e''. Therefore the temperament of this ſubordinate concord, in the full harmony K — III — V, is, in all caſes, the ſame with the contemporaneous temperament of the VIth.

In like manner, he will perceive that the temperament of the ſubordinate IIId, in the harmony of K — 4 — VI, is equal to the contemporaneous temperament of the III.

We alſo ſee, in general, that the whole harmony is more hurt when the temperer lies in the angle ECK, with the IIId tempered ſharp, than when it is in the angle ACE, when the IIId is flat; and that the ſum of all the temperaments of the concords with the key is the ſmalleſt when the IIIds are perfect. This ſyſtem of mean tones, with perfect IIIds, would therefore be the beſt, if the harmony of different concords were equally hurt by the ſame temperament.

...ce of ...eat uſe.

We do not know any thing that has been publiſhed on the ſcience of muſic that gives more general and ſpeedy inſtruction than this ſimple figure. If it be drawn of ſuch a ſize as to allow the comma EK to be divided into a number of equal parts, ſufficiently ſenſible, all trouble of calculation will be ſaved.

We would therefore propoſe to accompany this figure with proper ſcales.

The *firſt* ſcale ſhould have G g divided into $13\frac{1}{2}$ parts. This will expreſs the logarithmic meaſures of the temperaments mentioned in n° 63. a comma being $= 54$.

The *ſecond* ſcale ſhould have g G divided into 36 parts. This gives the beats made in 16 ſeconds by the notes c, g, when tempered by any quantity G g'.

The *third* ſcale ſhould have g G divided into 60 parts, for the beats made by the notes c, e, or the notes c, $\bar{a}$.

The *fourth* ſcale ſhould have g G divided into 72 parts. This gives the beats made by the key note C, with its minor third e^b.

The *fifth* ſcale ſhould have g G divided into 48 parts, for the beats made by the notes c, f.

The *ſixth* ſcale ſhould have g G divided into 89 parts, on which A a' is meaſured, to get the beats of the ſubordinate concord formed by g and e in the harmony of K — III — V.

And, *laſtly*, g G, divided into 80 parts, will give the beats made by f and $\bar{a}$ in the harmony of K — 4 — VI.

78 Harmonioufneſs, what?

We are ignorant of the immediate efficient cauſes of the pleaſure we receive from certain conſonances, and ſhould therefore receive, with ſatisfaction, any thing that can help us to approximate to a meaſure of its degrees. We know that, in fact, the pleaſantneſs of any individual concord increaſes as the undulations called *beats* diminiſh in frequency. It is probable that we ſhall not deviate very far from the truth, if we ſuppoſe the harmonioufneſs of an individual tempered concord to be proportional to the ſlowneſs of theſe undulations. But it by no means follows, that a tempered Vth and a IIId are equably pleaſant, each in its kind, when they beat equally ſlow. There is a difference *in kind* in the pleaſures of theſe concords: and this muſt ariſe from the peculiar manner in which the component pulſes of each concord divide each other. We are certain that this is all the difference that obtains between them in Nature. But the harmonioufneſs here ſpoken of is the arrangement which produces this pleaſure. We are intitled to ſay, that this is equal in two given inſtances, when the arrangements are preciſely ſimilar; and when the things arranged are the ſame, nothing ſeems to remain in which the inſtances can differ.

At any rate, it is of conſequence to be able to proportion and diſtribute theſe undulations at pleaſure. They are unpleaſant; and when reinforced by uniting, muſt be more ſo. The theory puts it in our power to prevent this union: perhaps by making them very unequal; or, if this ſhould give a chance of periodic accumulation, we may find it better to make them all equal. Surely to have all this in our power is very deſirable; and this is obtained by the theory of the beats of imperfect conſonances.

79 Temperament of a whole octave by beats.

But we are forgetting the proceſs of tuning, and have only tuned three or four notes of our octave. We muſt tune the reſt by conſidering their relation to notes already tuned. Thus, if $g\,c$ makes 36 beats in 16 ſeconds, F c ſhould make one third leſs, or about 24 in the ſame time; becauſe N in the formula is now 160 inſtead of 240. Proceeding in this way, we ſhall tune the octave C c moſt accurately as a ſyſtem of mean tones with perfect IIIds, by making the notes beat as follows. A point is put over the note that is to be tuned from the other, and a +, or a --, means that the concord is to be tempered ſharp or flat. Thus g is tuned from c,

Make	$c\,\dot{g}$ beat	—	36 times in 16 ſeconds
	$\dot{G}\,c$	+	36
	$G\,\dot{d}$	—	27, *i. e.* $\frac{3}{4}$ths of $\dot{g}\,c$
	$c\,\dot{f}$		48

Temperament of the Scale of Music.

Make $c\bar{a}$ beat +60 times in 16 seconds
ce 0, *i. e.* a perfect IIId
df※ 0
cg※ 0
ac※ 0
$\bar{b}^b f$ downward — 24, *i. e.* $\frac{3}{4}$ths of cg
$b^b\bar{b}^b$ 0, *i. e.* a perfect octave
$\bar{b}^b e^b$ downward—43, *i. e.* $\frac{4}{3}$ths of cg
C$\bar{c}$ 0 an octave.

Other processes may be followed, and perhaps some of them better than the process here proposed. Thus, b^b and e^b may be tuned as perfect IIIds to d and g downwards. Also, as we proceed in tuning, we can prove the notes, by comparing them with other notes already tuned, &c. &c. &c.

We have directed to tune the two notes b^b and e^b by taking the leading Vth downwards. We should have come at the same pipes in the character of a※ and d※ in the process of tuning upwards by Vths. But this would not have produced precisely the same sounds, although, in our imperfect instruments, one key must serve for a※ and b^b. By tuning them as here directed, they are better fitted for the places in which they will be most frequently employed in our usual modulations.

80 Another system very fit for our instruments.

It may reasonably be asked, Why so much is sacrificed in order to preserve the IIIds perfect? Were they allowed to retain some part of the sharp temperament that is necessary for preserving the Vths perfect, we should perhaps improve the harmony. And since enlarging the Vth makes the tone greater, and therefore the limma *mi fa* much smaller, it will bring it nearer to the magnitude of a half tone; and this will be better suited for its double service of the sharp of the note below, and the flat of the note above. Accordingly, such a temperament is in great repute, and indeed is generally practised, although the VIths and the subordinate chords of full harmony are evidently hurt by it. Even Dr Smith recommends it as well suited to our defective instruments, and gives an extremely easy method of executing it by means of the beats. His method is to make the Vth and IIId beat equally fast, along with the key, the Vth flat, and the IIId sharp. He demonstrates (on another occasion), that concords beat equally fast with the same bass when their temperaments are inversely as the major terms of their perfect ratios. Therefore draw EG, and divide it in p, so that Ep may be to pG as 3 to 5. Then draw Cp, cutting gG in g', and EK in e'; and this temperer will produce the temperament we want. It will be found, that Ee' and Gg' are each of them 32 of their respective scales. Fig 2.

Therefore make cg beat 32 times in 16 seconds
Gc 32
Gd 24
Gb 24, and tune $b\bar{b}$
$d\bar{a}$ 36, and tune $a\bar{a}$
df※ 36
ae 27
ac※ 27
$e\bar{b}$ $40\frac{1}{2}$, proving $b\bar{b}$
eg※ $40\frac{1}{2}$
Fc $21\frac{1}{3}$, and tune Ff
Fa beat $21\frac{1}{3}$, proving a
$b^b f$ $28\frac{1}{2}$, and tune $b^b\bar{b}^b$
$e^b\bar{b}^b$ $38\frac{1}{2}$
$c\bar{c}$ 0.

It may be proper to add to all these instructions a caution about the manner of counting the clock while the tuner is counting the beats. If this is to continue for 16 seconds, let the person who counts the clock say *one* at the beat he begins with, and then telling them over *to himself*, let him say *done* instead of 17. Thus 16 intervals will elapse while the tuner is counting the beats. Were he to begin to count at *one*, and stop when he hears sixteen, he would get the number of beats in 15 seconds only.

We do not hesitate to say, that this method of tuning by beats is incomparably more exact than by the mere judgment of the ear. We cannot mistake more than one beat. This mistake in the concord of the Vth amounts to no more than $\frac{1}{1073}$th of a comma; and in the IIId it is only $\frac{1}{130}$. 81

82 Practical instructions.

It may be objected that it is fit only for the organ and instruments of continued sounds, but will not do for the quickly perishing sounds of the harpsichord. True, it is the only method worthy of that noble instrument, and this alone is a title to high regard. But farther; the accuracy attainable by it, renders it the only method fit for the examination of systems of temperament. Even for the harpsichord it is much more exact, and more certain in its process, than any other. It does not proceed, by a random trial of a flattened series of Vths, and a comparison with the resulting IIId, and a second trial, if the first be unsatisfactory. It says at once, let the Vth beat so many times in 16 seconds. Even in the second method, without counting, and merely by the equality of the beats of the Vth and IIId, the progress is easy. Both are tuned perfect. The Vth is then flattened a little, and the IIId sharpened;—if the Vth beat faster than the IIId, alter it first.

All difficulty is obviated by the simple contrivance of a variable pendulum, already described. This may be made exact by any person that will take a little pains; and when once made, will serve for every trial. When the ball is set to the proper number, and the pendulum set a swinging, we can come very near the truth by a very few trials.

N. B. In tuning a piano forte, which has always two strings to a key, we must never attempt tuning them both at once; the back unison of both notes of the concord must be damped, by sticking in a bit of soft paper behind it.

We hope that the instructions now given, and the application of them to two very respectable systems of temperament, are sufficient for enabling the attentive reader to put this method of tuning successfully in practice, and that he perceives the efficiency of it for attaining the desired end. But before we take leave of it, we beg leave to mention another circumstance, which evinces the just value of the general theory of the beats of imperfect consonances as delivered by Dr Smith.

83 Origin of the Tartinian sounds.

These reinforcements of sound, which are called *beatings*, are noises. If any noise whatever be repeated, with sufficient frequency, at equal intervals, it becomes a musical note, of a certain determinate pitch. If it recur 60 times in a second, it becomes the note C *fa ut*, or the double ...

Temperament of the Scale of Music.

harpsichords, or the note of an open pipe eight feet long. Now there is a similar (we may call it the very same) reinforcement of sound in every concord. Where the pulse of one sound of the concord bisects the pulse of the other, the two sounds are more uniformly spread: but where they coincide, or almost coincide, the condensation of one undulation combines with that of the other, and there comes on the ear a stronger condensation, and a louder sound. This may be called a *noise*; and the equable and frequent recurrence of this noise should produce a musical note. If, for instance, *c* and *a* are sounded together: There is this noise at every third pulse of *c*, and every fifth pulse of *a*; that is, 80 times in a second. This should produce a note which is a 12th below *c*, and a 17th major below *a*; that is, the double octave below *f*, which makes 320 vibrations in a second. That is to say, along with the two notes *c* and *a* of the concord, and the compound sound, which we call the *concord of the VIth*, we should hear a third note FF in the bass. Now this is known to be a fact, and it is the grave harmonic observed by Romieu and Tartini about the year 1754, and verified by all musicians since that time. Tartini prized this observation as a most important discovery, and considered it as affording a foundation for the whole science of music. We see that it is all included in the theory of beats published five years before, namely, in 1749; and every one of these grave harmonics, or Tartinian sounds, as they have been called, are immediate consequences of this theory. The system of harmonious composition which Tartini has, with wonderful labour and address, founded on it, has therefore no solidity. It is, however, preferable to Rameau's, because it proceeds on a fact founded on the nature of musical sounds; whereas Rameau's is a mere whim, proceeding on a false assumption; namely, "that a musical sound is essentially accompanied by its octave, 12th, and 17th *in alto*."—This is not true, though such accompanyment be very frequent, and it be very difficult to prevent it. Mr Rameau ought to have seen this. Are these acute harmonics musical sounds or not? He surely will not deny this. Therefore they, too, are essentially accompanied by *their* harmonics, and this absolutely and necessarily *ad infinitum*; which is certainly absurd. We shall have a better occasion for considering this point when we describe the *Trumpet Marigni* in a future article.

We have taken notice of only two systems of temperament; both of them are systems of mean tones, and are in good repute as practicable methods. It would be almost an endless task to mention all the systems of temperament which have been proposed. Dr Smith, after having, with great ingenuity, appreciated the changes of harmoniousness that are induced on the different concords by the same temperament, and having assigned that proportion of temperament which renders them equally harmonious, each in its kind, gives a system of temperament, which he calls EQUAL HARMONY. Each concord (excepting the octave) is tempered in the inverse proportion of the product of the terms of its perfect ratio. It is very nearly equivalent to a division of the octave into 50 equal parts. We do not give any farther account of it here, although we think its harmony preferable to any thing that we have ever heard. We heard it, as executed for him, and under his inspection, by the celebrated harpsichord-maker Kirkmann, both when the instrument was yet in the hands of the maker, and afterwards by the ingenious author. We have also heard some excellent musicians declare, that the organ of Trinity college chapel at Cambridge was greatly improved in its harmony by the change made on its temperament under the inspection of Dr Smith. When we name Stanley, we presume that the authority will not be disputed. We mention this, because the writer in the Philosophical Transactions speaks of this system, with flattened major thirds, as of no value. But we do not give any farther account of it, because it is not suited to our instruments, which have but twelve sounds in the octave.

Temperament of the Scale of Music.

The reader will please to recollect, that the great object of temperament is twofold. First, to enable us to transpose music from one pitch to another, so that we may make any note of the organ the fundamental of the piece. This undoubtedly requires a system approaching to one of mean tones, because the harmony must be the same in every key. This requires temperament, because a sound must be occasionally considered, either as the sharp of the note below it, or the flat of the one above. This cannot produce perfect harmony, because the limma of the perfect diatonic scale is greater than a half tone. Thus a temperament is necessary merely for the sake of the melody. But, *secondly*, the nature of modern music requires every note to be accompanied, or considered as accompanied, with full harmony. This is, in fact, the same thing with modulating on every different note as a fundamental; but it requires a much closer attention to the perfection of the intervals, because a defect or excess in an interval that would scarcely offend the ear, if the notes were heard in succession, is quite intolerable when they are sounded together. Here the difference between the major and minor tone is of almost as great moment as the difference of the limma from a semitone. The second object, therefore, is to obtain, in the compass of three octaves, as many good concords of full harmony; that is, consisting of a fundamental with its major third and its fifth, erect or inverted, as possible. There is no other harmony, although our notes have frequently a different situation and appearance. 81

82 Maxims often para-[illegible] very fallacious.

It is no wonder that, in a subject where we are yet to seek for a principle, the attempts to attain this object have been very various, and very gratuitous. The mathematicians, even in modern times, have allowed themselves to be led away by fancies about the simplicity and consequent perfection of ratios; and having no clear principle, it is no wonder that some of their deductions are contrary to experience. According to Euler, those ratios which are most perfect, that is, most simple, admit of least temperament. The octave is therefore infinitely perfect; for it is allowed by all, that it must not have the smallest temperament. A Vth must be less tempered than a IIId. Even the practical musician thinks that he has tempered these two concords equally, when the offensive quality of each is made equally so; but in this case it is demonstrable, that the Vth has been much more tempered than the IIId. But this could not be discovered till we got the theory of beats

Most of the mathematical musicians adhered to systems of mean tones; or, which are equivalent to such systems, giving similar harmonies on every key of the harp-

Temperament of the Scale of Music. harpsichord. This is surely the most natural, and is peculiarly suggested by the transposing of music from one pitch to another: but they differ exceedingly, and without giving any convincing arguments, in their estimation of the effects of the same temperament on different concords. Much of this, we apprehend, arises from disposition. Persons of a gay disposition relish the harmony of the IIId, and prefer a sharp to a flat temperament of this concord. Persons of a more pensive disposition, prefer such temperaments as allow the minor thirds to be more perfect.

87 Equal harmony rejected. But there are many, eminent both as performers and as theorists, who reject any system which gives the same harmonies on every note of the octave. They observe, that in the progress of the cultivation of music in Europe, the melodies of all nations have gradually approached to a certain uniformity. Certain cadences, closes, strains, and phrases, are becoming every day more common; and even in the conduct of a considerable piece of music, and the gradual but slow passage of the modulation from one key into another, there is a certain regularity. Nay, they add, that this cannot be greatly deviated from without becoming very offensive. We may remain ignorant of the cause of this uniformity, but its existence seems to prove that it arises from some natural principle; and therefore it ought to be complied with, and our temperaments should be accommodated to it. The result of this uniformity in the music of our times is, that the modulation on some keys is much less frequent than on others, and this frequency decreases in a certain order. Supposing that we begin on C. A piece of plain music seldom goes farther than G and F. A little more fancy and refinement leads the composer into D, or into B♭, &c. &c. It would therefore be desirable to adjust our temperaments so, that the harmonics in C shall be the best possible, and gradually less perfect in the order of modulation. Thus we shall, in our general practice, have finer harmony than if it were made equal throughout the octave; because the unavoidable imperfections are thrown into the least frequented places of the scale. The practical musicians add to this, that by such a temperament the different keys acquire characters, which fit each of them more particularly for the expression of different sentiments, and for exciting different emotions. This is very perceptible in our harpsichords as they are generally tuned. The major key of A is remarkably brilliant, that of F is as remarkably simple, &c.

We cannot say that we are altogether convinced by these arguments. The violin is unquestionably the instrument of the greatest powers. A concert of instruments of this kind, unembarrassed by the harpsichord, or any instruments incapable of occasional temperament, is the finest music we have. The performers make no such degradations of harmony, but keep it as perfect as possible throughout; and a violin performer is sensible of violence and constraint when he accompanies a keyed instrument into these unfrequented paths. Let him play the same music alone, and he will play it quite differently, and much more to his own satisfaction. We imagine, too, that much of the uniformity spoken of is the result of imitation and fashion, and even of the temperaments that we have preferred. There is an evident distinction in the native music of different nations. An experienced musician will know, from a few bars, whether an air is Irish, Scotch, or Polish. This distinction is in the modulation; which, in those nations, follows different courses, and should therefore, on the same principle, lead to different temperaments.

With respect to the variety of characters given to the different keys, we must acknowledge the fact. We have tuned a piano forte in the usual manner; but, instead of beginning the process with C, we began it with D. An excellent performer of voluntaries sat down to the instrument, and began to indulge his rich fancy; but he was confounded at every step: he thought the instrument quite out of tune. But when he was informed how it had been tuned, and then tried a known plain air on it, he declared it to be perfectly in tune. It is still very doubtful, however, whether we should not have much finer music, by equalising the harmony in the different keys, and trusting for the different expression so much spoken of to a judicious mixture of other notes called *discords*.

88 Cause of this uncertainty now removed by Dr Smith's theory. After all, the great uncertainty about the most proper temperament has remained so long undetermined, because we had no method of executing with certainty any temperament that was offered to the public. What signifies it on what principle it may be proper to flatten a Vth one fifth of a comma, and sharpen a VIth one seventh of a comma, unless we are able to do both the one and the other? Till Dr Smith published the theory of beats, the monochord was the only assistance we had: but however nicely it may be divided, it is scarcely possible to make the moveable bridge so steady and so accurate in its motion, that it will not sensibly derange the tension of the string. We have seen some very nice and costly monochords; but not one of them could be depended on to one-eighth of a comma. Even if perfect, they give but momentary sounds by pinching. The bow cannot be trusted, because its pressure changes the tension. Mr Watt's experiments with his monochord of continued sound shewed this evidently. A pitch-pipe with a sliding piston promises the greatest accuracy; but we are sadly disappointed, because the graduation of the piston cannot be performed by any mathematical rule. It must be pushed more than half way down to produce the octave, more than one-third to produce the Vth, &c. and this without any rule yet discovered. Thanks to Dr Smith we can now produce an instrument tuned exactly, according to any proposed system, and then submit it to the fair examination of musicians. Even the speculatist may now form a pretty just opinion of the merits of a system, by calculating, or measuring by such scales as we have proposed, the beats produced by the tempered concords in all parts of the octave. No one who has listened with attention to the rattling beats of a full organ, with its twelfth and sesquialter stops all sounding, will deny that they are hostile to all harmony or good music. We cannot be much mistaken in preferring any temperament in proportion as it diminishes the number of those beats. We should therefore examine them on this principle alone; attending more particularly to the beats of the third major, because these are in fact the loudest and most disagreeable; and we must not content ourselves with the beats of each concord with the fundamental of the full harmony, whether K—III—V, or K—4—VI, or K—3—V, or K—4—6, which sometimes occurs. We must attend equally to the beats of the two notes

Tempera-ment of the Scale of

of accompanyment with each other: theſe are generally the moſt faulty.

This examination is neither difficult nor tedious. 1. Write down, in one column, the lengths of the ſtrings or diviſions of the monochord; in another write their logarithms; in a third the remainders, after ſubtracting each from the logarithm of the fundamental. 3. Have at hand a ſimilar table for the perfect diatonic ſcale. 4. Compare theſe, one by one, and note the difference, + or —, in a 4th column. Theſe are the temperaments of each note of the ſcale. 5. Compare every couple of notes which will compoſe a major or minor third, or a fifth, by ſubtracting the logarithm of the one note from that of the other. The differences are the intervals tempered. 6. Compare theſe with the perfect intervals of the diatonic ſcale, and note the differences, + or —, and ſet them down in a fifth column. Theſe are all the temperaments in the ſyſtem. 7. If we have uſed logarithms conſiſting of five decimal places, which is even more than ſufficient, conſider theſe numeral temperaments as the q of the formula given in n° 65. for calculating the beats, and then p is always = 540. Or we may make another column, in which the temperaments are reduced to ſome eaſy fraction of a comma.

90 ſrom Young.

We ſhall content ourſelves with giving one example; the temperament propoſed by Mr Young in the Philoſophical Tranſactions for 1800. It is contained in the following table.

1.	2.	3.	4.	5.		
				IIIds upward on		
C	100000	5.00000		C	135	Sharp.
C※	94723	4.97645	2355	G. F.	190	
D	89304	4.95087	4913	D. B♭	245	
E♭	83810	4.92330	7670	A. E♭	346	
E	79752	4.90174	9826	E. A♭	448	
F	74921	4.87461	12539	B. C※	494	
F※	71041	4.85151	14849	F※	540	
G	66822	4.82492	17508	3ds upward on		
G※	63148	4.80036	19964	A. E.	236	Flat.
A	59676	4.77580	22420	D. B.	291	
B♭	56131	4.74921	25079	G. F※	346	
B	53224	4.72610	27390	C. C※	448	
C	50000	4.69897	30103	F. G※	494	
				B♭. E♭	540	

Vths upward on

E♭. G※. C※. F※	perfect	Flat.
F. B♭. E. B	46	
C. G. D. A	116	

Interval of a comma	540
minor third	7918
major third	9691
fifth	17609

The firſt column of the above table contains the ordinary deſignations of the notes. The ſecond contains the correſponding lengths of the monochord The third contains the logarithms of column ſecond. The fourth contains the difference of each logarithm from the firſt. The next column contains, firſt, the temperaments of all the major thirds, having for their loweſt note the ſound correſponding to the letter. Thus 494, or $\frac{494}{540}$ of a comma, is the temperament of the IIId, B — D※, and C※ — F. Secondly, it contains all the minor thirds formed on the notes repreſented by the letters. The column below contains the temperaments of the Vths. *N. B.* Theſe temperaments are calculated by the author. We have found ſome of them a little different. Thus we make the temperament of C — G only 118. Below this we have ſet down the meaſures of the perfect intervals, which are to be compared with the differences of the logarithms in column third.

Temperament of the Scale of Muſic, [illegible]

91 Syſtem Kirnberger.

We preſume not to decide on the merits of this temperament: Only we think that the temperaments of ſeveral thirds, which occur very frequently, are much too great; and many inſtances of the 6th, which is frequent in the flat key, are ſtill more ſtrongly tempered. A temperament, however, which very nearly coincides with Dr Young's, has great reputation on the continent. This is the temperament by Mr Kirnbergher, publiſhed at Berlin in 1771, in his book called *Die Kunſt des reinen Satzes in der Muſik.* The eminent mathematician Major Templehoff has made ſome important obſervations on this temperament, and on the ſubject in general, in an eſſay publiſhed in 1775, Berlin. Dr Young's is certainly preferable.

The monochord is thus divided by Kirnbergher

C =	1,0000	F =	7500	B♭ =	5925
C※	9492	F※	7111	B	5313
D	8889	G	6667		5000
E♭	8437	G※	6328		
E	8000	A	5963		

We conclude this article (perhaps too long) by earneſtly recommending to perſons who are not mathematically diſpoſed, the ſliding ſcales, either circular or rectilineal, containing the octave divided into 301 parts; and a drawing of fig. 2. on card paper, of proper ſize, having the quarter comma about two inches, and a ſeries of ſcales correſponding to it. This will ſave almoſt the whole of the calculation that is required for calculating the beats, and for examining temperaments by this teſt. To readers of more information, we earneſtly recommend a careful peruſal of Smith's Harmonics, ſecond edition. We acknowledge a great partiality for this work, having got more information from it than from all our patient ſtudy of the moſt celebrated writings of Ptolemy, Huyghens, Euler, &c. It is our duty alſo to ſay, that we have got more information concerning the muſic of the Greeks from Dr Wallis's appendix to his edition of Porphyrius's Commentary on Ptolemy's Harmonics, than from any other work

TEMPLARS. In the account of this order, which is publiſhed in the *Encyclopædia*, we have, with many others, ſuppoſed that the guilt of which they were accuſed at the ſuppreſſion of the order was leſs enormous than their enemies alleged. For the honour of human nature, we are ſtill unwilling to believe that this was not the caſe. Juſtice, however, compels us to admit, that the Abbé Barruel has brought together ſuch a cloud of witneſſes againſt the Templars, that we know not how to reſiſt their evidence; and that he has completely proved, that *Philip le Bel* was not influenced by avarice when he ſuppreſſed that order in France "It has been ſaid, that he and Clement V. had concerted between them the diſſolution of the Templars. The falſity of ſuch an aſſertion is evident on the inſpection of their letters. Clement V. at firſt will give no credit

dict to the accusations against the Templars; and even when he receives incontestable proofs from Philip le Bel, he had still so little concerted the plan with that Prince, that every step taken by the one or the other occasions disputes on the rights of the church or of the throne.

"It was also said, that the king wished to seize on the great riches of these knights: but at the very commencement of his proceedings against the order, he solemnly renounced all share in their riches; and perhaps no Prince in Christendom was truer to his engagement. Not a single estate was annexed to his domain; and all history bears testimony to the fact.

"We next hear of a spirit of revenge which actuated this Prince; and during the whole course of this long trial, we do not hear of a single personal offence that he had to revenge on the Templars. In their defence, not the most distant hint, either at the revengeful spirit, or at any personal offence against the king, is given: so far from it, until the period of this great catastrophe, the grand master of the order had been a particular friend of the king's, who had made him godfather to one of his children.

"In fine, the rack and torture is supposed to have forced confessions from them which otherwise they never would have made; and in the minutes, we find the avowal of at least 200 knights all made with the greatest freedom, and without any coercion. Compulsion is mentioned but in the case of one person; and he makes exactly the same avowal as 12 other knights, his companions, freely made (A). Many of these avowals were made in councils where the bishops begin by declaring, that all who had confessed through fear of the torture should be looked upon as innocent, and that no Knight Templar should be subjected to it (B). The Pope Clement V. was so far from favouring the king's prosecutions, that he began by declaring them all to be void and null. He suspended the archbishops, bishops, and prelates, who had acted as inquisitors in France. The king accuses the Pope in vain of favouring the Templars; and Clement is only convinced after having been present at the interrogatories of 72 knights at Poictiers, in presence of many bishops, cardinals, and legates. He interrogated them, not like a judge who sought for criminals, but like one who wishes to find innocent men, and thus exculpate himself from the charge of having favoured them. He hears them repeat the same avowals, and they are freely confirmed. He desired that these avowals should be read to them after an interval of some days, to see if they would still freely persevere in their depositions. He hears them all confirmed. *Qui perseverantes in illis, eas expresse et sponte prout recitatæ fuerant approbårunt.* He wished still further to interrogate the grand master and the principal superiors, *præceptores majores*, of the divers provinces of France, Normandy, Poitou, and of the Transmarine countries. He sent the most venerable persons to interrogate those of the superiors, whose age or infirmities hindered them from appearing before him. He ordered the depositions of their brethren to be read to them, to know if they acknowledged the truth of them. He required no other oath from them than to answer freely and without compulsion; and both the grand master and the superiors of these divers provinces depose and confess the same things, confirm them some days after, and approve of the minutes of their depositions taken down by public notaries. Nothing less than such precautions could convince him of his error: it was then only that he revoked his menaces and his suspension of the French bishops, and that he allows the king to proceed in the trials of the Templars. Templars

"Let such pretexts be forgotten, and let us only dwell on the avowals which truth alone forced from these criminal knights.

"Their depositions declare, that the Knights Templars, on their reception, denied Christ, trampled on the cross, and spit upon it; that Good Friday was a day which was particularly consecrated to such outrages; that they promised to prostitute themselves to each other for the most unnatural crimes; that every child begotten by a Templar was cast into the fire; that they bound themselves by oath to obey, without exception, every order coming from the grand master; to spare neither sacred nor prophane; to look upon every thing as lawful when the good of the order was in question; and, above all, never to violate the horrible secrets of their nocturnal mysteries, under pain of the most terrible chastisements (C).

"In making their depositions, many of them declared they had only been forced into these horrors by imprisonment and the most cruel usage; that they wished, after the example of many of their brethren, to pass into other orders, but that they did not dare, fearing the power and vengeance of their order; that they had secretly confessed their crimes, and had craved absolution. In this public declaration, they testified, by their tears, the most ardent desire of being reconciled to the church.

"All repeat the same deposition, except three, who declare they have no knowledge of the crimes imputed to their order. The Pope, not content with this information taken by men of religious orders and by French noblemen, requires that a new trial should take place in Poitou before cardinals and others whom he himself nominates: Again, with the same freedom, and for the third time, the grand master and other chiefs, in presence of Clement V. repeat their depositions. Molay even requested, that one of the lay brothers, who was about his person, should be heard, and this brother confirms the declaration. During many years these informations were continued and renewed at Paris, in Champagne, in Normandy, in Quercy, in Languedoc, in Provence. In France alone, above 200 avowals of the same nature are to be found: nor did they vary in England, where, at the synod of London held in 1311, 78 English knights were heard, and two whole months were spent in taking informations and in verifying their declarations. Fifty-four Irish were also heard, and many Scotch, in their respective countries. It was in consequence of these declarations that the order of the Templars was abolished in those kingdoms, and that the parliament

(A) *Layette*, N° 20. *Interrog. made at Caen.*

(C) See the *Vouchers brought by Dupuy*, and *Extract of the Registers.*

Templars, Templeman.

parliament disposed of their goods (D). The same declarations were taken and proved in Italy, at Ravenna, at Bologna, at Pisa, and at Florence, though in all these councils the prelates were very ready to absolve all those knights who could succeed in their justifications.

"I would willingly assert (continues the Abbé), that it was the smaller part of the Templars who suffered themselves to be carried away by such abominations. Some even at Paris were declared innocent. In Italy a still greater number were absolved; of all those who were judged at the councils of Mayence and Salamanca, none were condemned: and hence we may conclude, that of the 9000 houses belonging to the order, many had not been tainted, and that whole provinces were to be excepted from the general stain of infamy. But the condemnations, the juridical depositions, the method of initiating the knights, almost become general; the secrecy of their receptions, where neither prince, nor king, nor any person whatever, could be present during the last half century, are so many testimonies which corroborate the divers accusations contained in the articles sent to the judges; that is to say, that at least two-thirds of the order knew of the abominations practised without taking any steps to extirpate them. *Quod omnes, vel quasi duæ partes ordinis scientes dictos errores corrigere neglexerint.*

"This certainly cannot mean that two thirds of the knights had equally partaken of these abominations. It is evident, on the contrary, that many detested them as soon as they were acquainted with them; and that others only submitted to them, though initiated, after the harshest treatment and most terrible threats. Nevertheless, this proves, that the greatest part of these knights were criminal, some through corruption, others through weakness or connivance; and hence the dissolution of the order became necessary."

TEMPLEMAN (Peter), M. D. the son of an eminent attorney at Dorchester in the county of Dorset, by Mary daughter of Robert Haynes, was born March 17, 1711, and was educated at the Charter-house (not on the foundation), whence he proceeded to Trinity-college, Cambridge, and there took his degree of B. A. with distinguished reputation. During his residence at Cambridge, by his own inclination, in conformity with that of his parents, he applied himself to the study of divinity, with a design to enter into holy orders; but after some time, from what cause we know not, he altered his plan, and applied himself to the study of physic. In the year 1736, he went to Leyden, where he attended the lectures of Boerhaave, and the professors of the other branches of medicine in that celebrated university, for the space of two years or more. About the beginning of 1739, he returned to London, with a view to enter on the practice of his profession, supported by a handsome allowance from his father. Why he did not succeed in that line was easy to be accounted for by those who knew him. He was a man of a very liberal turn of mind, of general erudition, with a large acquaintance among the learned of different professions, but of an indolent, inactive disposition; he could not enter into juntos with people that were not to his liking; nor cultivate the acquaintance to be met with at tea-tables; but rather chose to employ his time at home in the perusal of an ingenious author, or to spend an attic evening in a select company of men of sense and learning. In this he resembled Dr Armstrong, whose limited practice in his profession was owing to the same cause. In the latter end of the year 1750 he was introduced to Dr Fothergill by Dr Cuming, with a view of instituting a Medical Society, in order to procure the earliest intelligence of every improvement in physic from every part of Europe. At the same period he tells his friend, "Dr Mead has very generously offered to assist me with all his interest for succeeding Dr Hall at the Charter house, whose death has been for some time expected. Inspired with gratitude, I have ventured out of my element (as you will plainly perceive), and sent him an ode." Dr Templeman's epitaph on Lady Lucy Meyrick (the only English copy of verses of his writing that we know of), is printed in the eighth volume of the "Select Collection of Miscellany Poems, 1781." In 1753 he published the first volume of "Curious Remarks and Observations in Physic, Anatomy, Chirurgery, Chemistry, Botany, and Medicine; extracted from the History and Memoirs of the Royal Academy of Sciences at Paris;" and the second volume in the succeeding year. A third was promised, but we believe never printed. It appears, indeed, that if he had met with proper encouragement from the public, it was his intention to have extended the work to twelve volumes, with an additional one of index, and that he was prepared to publish two such volumes every year. His translation of "Norden's Travels" appeared in the beginning of the year 1757; and in that year he was editor of "Select Cases and Consultations in Physic, by Dr Woodward," 8vo. On the establishment of the British Museum, in 1753, he was appointed to the office of keeper of the reading-room, which he resigned on being chosen, in 1760, secretary to the then newly instituted Society of Arts, Manufactures, and Commerce. In 1762, he was elected a corresponding member of the Royal Academy of Science of Paris, and also of the Œconomical Society at Berne. Very early in life Dr Templeman was afflicted with severe paroxysms of an asthma, which eluded the force of all that either his own skill, or that of the most eminent physicians then living, could suggest to him; and it continued to harass him till his death, which happened September 23, 1769. He was esteemed a man of great learning, particularly with respect to languages; spoke French with great fluency, and left the character of a humane, generous, and polite member of society.

Templeman, Terané.

TERANE', a town in Egypt, situated on what Mr Browne calls the *left* of the most western mouth of the Nile, at a very small distance from the river. Its latitude is 30° 24'. The buildings are chiefly unburned brick, though there are also some of stone. The town and district, containing several villages, belonged, before the French invasion, to Murad Bey, who usually entrusted its government, and the collection of its revenue, to one of his Cashefs. That revenue arises principally from natrôn (See NATRUM, *Encycl.*), found in

(D) Vide *Valsinger in Edvardum* II. *et Ypodigma Neustriæ apud Dupuy.*—*Essai de Fred. Nicolai.*

in great quantities in certain lakes about thirty five miles from Terané; and it is on account of these lakes only that the town is worthy of notice in this work; for though there are many columns in its neighbourhood, which indicate the site of ancient structures, none of them have inscriptions ascertaining their antiquity.

The eastern extremity of the most western lake Mr Browne found to be 30° 31′ North. No vegetation appears, except reeds, on the margin of the lake, which is very irregular in its form; so that it is not easy to say what may be the quantity of ground covered with water. It is higher in winter than in summer; and when it was visited by our author, its breadth did not exceed a mile, though its length was nearly four. Towards the end of the summer, it is said, these lakes are almost dry; and the space that the water has retired from is then occupied by a thick deposition of salt. Not far removed from the eastern extremity, a spring rises with some force, which much agitates the rest of the water. Close to that spring the depth was far greater than Mr Browne's height; in other parts it was observable that it did not generally exceed three feet. The thermometer near this spring stood at 76, while in the open air it was 87. The more western lake differs not materially from the eastern in size, form, or productions. The colour of the water in both is an imperfect red; and where the bottom is visible, it appears almost as if covered with blood. Salt, to the thickness of five or six inches, lies constantly in the more shallow parts. The surface of the earth, near the lake, partakes more or less generally of the character of natrôn, and, in the parts farthest removed, offers to the foot the slight resistance of ploughed ground after a slight frost. The soil is coarse sand. The water of the lake, on the slightest evaporation, immediately deposits salt. There is a mountain not far from the lakes, where natrôn is found in insulated bodies, near the surface, of a much lighter colour than that produced in the lake, and containing a greater portion of alkali. How thick the substance of natrôn commonly is in the lake, our author did not accurately determine; but those employed to collect it report, that it never exceeds a cubit, or common pike; but it appears to be regenerated as it is carried away. If ever it should be brought to supersede the use of barilla, the quantity obtainable seems likely to answer every possible demand.

TEREBRATULÆ (ANOMIÆ, *Lin.* see that article *Encycl.*) have been supposed not to exist now but as petrified shells. This, however, is a mistake. The anomia is an inhabitant of every region, and has existed in every age. As many terebratulæ were caught by Perouse's people during his voyage of discovery, and as Lamanon the naturalist thought they should be considered as a genus by themselves, he has given us the following description of the *anomia*, or, as he calls it, *terebratula*, on the coast of Tartary:

The length of the shell varies from six to twenty lines, and its breadth from five to eighteen; there are, however, considerable varieties of proportion between different individuals, besides those arising from the different ages of the animal. It would be improper, therefore, to distinguish the various species of anomiæ by the proportion of their shells. The waving lines on the edges of the shell are equally defective, as distinctive characters; for our author observed in the same species the shell approaching or receding indifferently from the circular form, and, in some, the edges of the valves are on the same plane; whereas in others, one of the valves forms a salient angle in the middle of its curve, and the other a re-entering angle

Terebratulæ.

The shell is of a moderate thickness, about that of a common muscle; it is somewhat transparent, convex like the cockle: neither of the shells is more sensibly arched than the other; that, however, which has the spur, is rather the most so, especially in the superior part.

On the surface of the shell are seen a number of slight transverse depressions, of a semicircular waved form, which reach the part where the shell ceases to be circular, in order to form the angle which supports the summit.

These striæ are covered with a very thin and slightly-adhering periosteum; in some specimens there are from one to three shallow broad depressions, radiating insensibly from the centre of the shell, and becoming more marked as they approach the edges, where they form, with the corresponding parts of the other shell, those salient and re-entering angles which have been mentioned. The periosteum is rather more firmly fixed on the latter angles than on the former.

The shells are equal in the rounded part of their edge, and close very exactly; however, towards the summit, the spur of one of the shells reaches considerably beyond the other shell, consequently they are unequal, as in oysters.

The spur, or summit, is formed by the folding from within of the edge of the shell, and the elongation of its upper part. The folded edges form an oval aperture of a moderate size, through which the animal extends the muscle, by means of which it attaches itself to other substances. This shell is not, therefore. perforated, as its name of terebratula would seem to imply, the opening not being worked in one of the shells, but formed by the elongation of one shell, the folding in of its edges, and the approach of the other shell. The summit is not pointed, but round.

The ligament, as in the oyster, is placed between the summits, and does not appear on the outside; it adapts itself to the pedicle of the animal. As the summit takes up a considerable part of the shell, the valves are only capable of opening a very little without running the risk of being broken. It is very firm, though slender, and not easily to be discovered, being fixed in a small groove, which is filled up when the shell is shut by the corresponding part of the opposite shell. This ligament preserves its texture, even for a considerable time after the shell is emptied and become dry.

Oysters are without a hinge, the teeth which form it in many other shells not existing in them. The anomia has been considered as an oyster, because its hinge or teeth have not been examined: they are not visible indeed in the fossile specimens; but in opening them when alive, the teeth composing the hinge are sufficiently visible, being even much larger than in the greater part of bivalve shells. The fossil terebratulæ are almost always found with their shells closed; whereas the other bivalves have usually theirs either open or separated: the reason of this seems to arise from the nature of the hinge, that of the anomia not allowing it

to

Terebratulæ.

to separate, and the ligament, which is very tight, contributing to keep the two shells united. The teeth which form the hinge of the anomia approach very near to those of the *spondyle*, described by M. Adanson. In this last they are formed by two rounded projections, and in the anomia by the same a little elongated. It is above these teeth that the ligament is placed in the larger shell: there are between it and the teeth two cavities, one on each side, which serve to receive the teeth of the other valve. The teeth of the larger shell have, besides, a slight projection, which fits into a longitudinal furrow in the other shell in front of the teeth.

The substance which covers the inside of the shell holds, as in oysters, a middle place between *nacre* and the interior substance of shells, which are destitute of it. The degree of its lustre, polish, and thickness, varies with the age and circumstances of individuals.

The colour of the teeth is always white; that of the outer surface of the shell verges more or less to the ochry red, especially on the border. The inside has also a very slight tint of this colour, on a varying greyish-white ground.

There is visible on each side of the shell the impression of two very distinct tendons; a circumstance which forms a very essential difference between this genus and that of the oyster: this latter having only one tendon arising from the middle of the body. The impressions of the tendon in the largest shell are oblong, situate near the summit, and hollowed; each of them has curved transverse ridges, divided into two parts by a longitudinal furrow, representing the wings of certain insects. In the other valve the insertions have a different form; their situation is the same, but they are very irregularly rounded and encompassed by two fulcations, which are separated from each other by an intervening ridge, and then are continued in a right line towards the opening of the shell as far as about two thirds of its length. That part of the summit of the shell along which the pedicle of the animal passes, is longitudinally striated in the larger shell, of which the middle stria is the deepest: the longitudinal striæ are divided into equal parts by a transverse depression. There are no similar marks on the other shell.

Our author dissected the animal itself, and found what he calls the *manteau* of the anomia, formed of a very fine membrane, lining the inside of both shells, and containing the body of the animal. Its origin is of the same breadth as the hinge of the shell, whence it divides into two lobes, lining both the shells: it forms, therefore, only a single aperture, terminating at each end of the hinge, and of the same breadth with the interior surface of the shell: it appears to have only one trachea, which is formed by the two lobes of the manteau.

Our naturalist having opened the shell, divided the ligament as delicately as possible, unfixed the hinge, and detaching from the larger shell the lobe of the manteau, turned over the body of the animal. This operation exposed to view the large muscles which adhered to the shell; they are soft, membranous, and, as it were, fleshy on the inside, being covered with small sanguiferous glands. From the lower part of each muscle there proceeds a pretty strong tendon, which reaches to the extremity of the manteau; they run parallel to the edge of the shell, and at a considerable distance from each other; and are each enclosed in a sort of flatted sac, of the shape of a ribbon, which is filled with a red viscid matter. It appears that the place of insertion of the muscles, as well as the muscles themselves, which extend along the lobe of the manteau, furnish real blood, which is contained in three small fleshy red glandular bodies of unequal size, which are visible after having taken off the muscles; perhaps these constitute the heart of the animal.

The muscles which are inserted into the other shell are also divided into several parts: some are seen extending along the corresponding lobe of the manteau; many others rise up in a kind of tuft, which is fixed into the shell above: some again subdivide into such minute ramifications as not to allow of tracing their course, even with the assistance of a microscope; but others, more apparent, contribute to the formation of the pedicle which passes through the opening left between the two shells, is connected to each of them by several fibres, and fixes itself to some external body, principally to other bivalves. The muscles of the anomia have therefore three attachments, namely, to the inner surface of each shell, and to some external body.

The form of the pedicle is cylindrical, being enclosed in a muscular substance, which contains several fibres; it is from a line to a line and a half long, and two thirds in diameter. It adheres so forcibly to different substances, as that the animal, and all the muscles which contribute to the formation of the pedicle, may more easily be torn through than the pedicle detached from the place of its adhesion. The glutinous substance which connects them to each other, resists even the heat of boiling water. It is by means of this pedicle that the animal raises its shell so as to be, while in the water, in a position inclined to the horizon. The smallest valve is always the lowest, being that upon which the animal rests; the superior one being the larger, and serving as a covering. Our author thinks the animal has the power of loco-motion.

After raising the lobe of the manteau he observed the ears. They are large, composed of two membranaceous laminæ on each side, of which the superior is the narrower. These laminæ are connected to each other by a thin membrane, so as to form only a single pouch. They have on their edges long fringes, which hang loose upon the manteau; but a very remarkable circumstance is, that their ears are supported by little bones like those of fish. The form of the ears is that of an arch; they are separated from each other on their lower part, where the fringes are the longest; so that the two ears on one side are perfectly distinct from those on the other side. The commencement of the ears is at the teeth of the hinge.

Between the ears are situate the stomach, œsophagus, and mouth; the whole forming a triangle, of which the mouth is the base. It is placed at the side of the hinge, and consists of a large transverse opening without lips or jaw-bone. The œsophagus is very short, but is capable of elongation when the animal opens its mouth. The stomach, which is of the shape of a pointed sac, is connected by a membrane to the bones of the ear. On opening the stomach, he found a small shrimp half digested.

At the bottom of the stomach is seen the intestine, of which it is, as it were, a continuation. It is extremely short, not exceeding half a line in a shell fifteen

Terebratulæ, Ternai.

lifice across, and is composed of a very slender membrane. The excrements are discharged upon the lobes of the manteau, but they are easily thrown out by the motions of the two lobes.

The little bones of the ears, already mentioned, had not formerly been observed in any of the testaceous animals; whence the terebratulæ approach nearer to fish than the inhabitants of any other shell. In the anomiæ which are preserved in cabinets, there is found only a very small portion of these bones, whence they have obtained the improper appellations of *tongue* or *fork*, which indicate only the form of the fragments, and not their use.

The small bones of the ears are composed of several pieces, the principal of which is of an oval form; it springs from the side of the hinge, of which it appears to be a continuation; thence it extends about two-thirds of the breadth of the shell, where it is reflected, and rests against the upper part of the fork, to the branches of which it is united by a simple superposition; a kind of articulation very common among the numerous small bones that compose the heads of fish. The fork extends from the summit a little more than one-third of the breadth of the shell: it is formed by a pivot which divides into two long and pointed branches; these are remarkably brittle, and support the extremities of the bones of the larger ears. The lamina, which composes a second set of ears, rests upon a curved bone, which on one side is attached to the inferior internal part of the bone of the larger ears, and on the other reaches to the side of the mouth of the animal, where it is united to another flat little bone, which is applied to a similar bone on the other side. These last little bones are exactly below the membrane which forms the mouth. All these bones are flat, very brittle, and surrounded with fibres and membranes. By their articulations the ears are enabled to move; they also support the body of the animal, which touches neither of the shells, but remains between them as upon tressels. The space between the branches of the bones of the ears is filled up with a transparent firm membrane; at the base of the fork is a similar one, and a perpendicular partition dividing the space occupied by the body of the animal from the rest of the shell. There are two orifices in this membrane communicating with the space between the two lobes of the manteau, and which serves as a trachea; for we have remarked, in the description of the manteau, that the two lobes are entirely separated from each other, and therefore do not form a real trachea.

From this description, it follows that the anomia ought to be separated from the genus oyster, since it has a toothed hinge, several ligaments, and an interior organization wholly different; neither ought it to be confounded with the cockle, the shells of which are both equal, and are destitute of any sensible periosteum, without reckoning other differences. It has still less analogy with the other bivalves, and therefore ought to constitute a peculiar genus; the species of which, both fossil and living, are very numerous.

See Plate XLIII. where fig. 1. is a front view of a terebratula of middle size. Fig. 2. is a view of the internal structure.—A A, laminæ of the superior ears—B B, laminæ of the inferior—C, the stomach—D, the anus—E E, the manteau—F, the œsophagus.

TERNAI, the name given by Perouse to a very fine bay which he discovered on the coast of Tartary, in Lat. 45° 13′ North, and in Long. 135° 9′ East from Paris. The bottom is sandy, and diminishes gradually to six fathoms within a cable's length of the shore. The tide rises five feet; it is high water at $8^h\ 15^m$ at full and change; and the flux and reflux do not alter the direction of the current at half a league from the shore.

"Five small creeks (says La Perouse), similar to the sides of a regular polygon, form the outline of this roadstead; these are separated from each other by hills, which are covered to the summit with trees. Never did France, in the freshest spring, offer gradations of colour of so varied and strong a green; and though we had not seen, since we began to run along the coast, either a single fire or canoe, we could not imagine that a country so near to China, and which appeared so fertile, should be entirely uninhabited. Before our boats had landed, our glasses were turned towards the shore, but we saw only bears and stags, which passed very quietly along the sea side. The same plants which grow in our climates carpeted the whole soil, but they were stronger, and of a deeper green; the greater part were in flower. Roses, red and yellow lilies, lilies of the valley, and all our meadow flowers in general, were met with at every step. Pine trees covered the tops of the mountains; oaks began only half way down, and diminished in strength and size in proportion as they came nearer the sea; the banks of the rivers and rivulets were bordered with willow, birch, and maple trees, and on the skirts of the forests we saw apple and medlar trees in flower, with clumps of hazle nut trees, the fruit of which already made its appearance. Our surprise was redoubled, when we reflected on the population which overburdens the extensive empire of China, so that the laws do not punish fathers barbarous enough to drown and destroy their children, and that this people, whose polity is so highly boasted of, dares not extend itself beyond its wall, to draw its subsistence from a land, the vegetation of which it would be necessary rather to check than to encourage. At every step after we had landed, we perceived traces of men by the destruction they had made; several trees, cut with sharp-edged instruments; the remains of ravages by fire were to be seen in several places, and we observed some sheds, which had been erected by hunters in a corner of the woods. We also found some small baskets, made of the bark of birch trees, sewed with thread, and similar to those of the Canadian Indians; rackets for walking on the snow; in a word, every thing induced us to think that the Tartars approach the borders of the sea in the season for hunting and fishing; that they assemble in colonies at that period along the rivers; and that the bulk of the nation live in the interior of the country on a soil perhaps better calculated for the multiplication of their immense flocks and herds."

Our navigators caught in the bay vast quantities of fine fish, such as cod, harp-fish, trout, salmon, herrings, and plaice; but though game was plenty on shore, they had no success in hunting. The meadows, so delightful to the sight, could scarce be crossed; the thick grass was three or four feet high, so that they found themselves in a manner buried in it, and they were under the perpetual dread of being bitten by serpents, of which

which they saw a great number on the banks of the rivulets. They found, however, immense quantities of small onions, sorrel, and celery; which, together with the fresh fish, served as antidotes against the scurvy.

TERRE-PLEIN, or TERRE PLAIN, in fortification, the top, platform, or horizontal surface of the rampart, upon which the cannon are placed, and where the defenders perform their office. It is so called because it lies level, having only a little slope outwardly to counteract the recoil of the cannon. Its breadth is from 24 to 30 feet; being terminated by the parapet on the outer side, and inwardly by the inner talus.

TERRELLA, or little earth, is a magnet turned of a spherical figure, and placed so as that its poles, equator, &c. do exactly correspond with those of the world. It was so first called by Gilbert, as being a just representation of the great magnetic globe we inhabit. Such a terrella, it was supposed, if nicely poised, and hung in a meridian like a globe, would be turned round like the earth in 24 hours by the magnetic particles pervading it; but experience has shewn that this is a mistake.

TETRAEDRON, or TETRAHEDRON, in geometry, is one of the five Platonic or regular bodies or solids, comprehended under four equilateral and equal triangles. Or it is a triangular pyramid of four equal and equilateral faces.

TETRAGON, in geometry, a quadrangle, or a figure having four angles. Such as a square, a parallelogram, a rhombus, and a trapezium. It sometimes also means peculiarly a square.

TETRAGON, in astrology, denotes an aspect of two planets with regard to the earth, when they are distant from each other a fourth part of a circle, or 90 degrees. The tetragon is expressed by the character □, and is otherwise called a square or quartile aspect.

THEBES, in Egypt. Having in the *Encyclopædia* given Mr Bruce's account of this ancient city, which represents it as having been a paltry place, so contrary to the description of Homer, justice to the father of poetry requires that we here notice what has been said of it by a subsequent traveller, who remained three days among its ruins. According to Mr Browne, "the massy and magnificent forms of the ruins that remain of ancient Thebes, the capital of Egypt, the city of Jove, the city with 100 gates, must inspire every intelligent spectator with awe and admiration. Diffused on both sides of the Nile, their extent confirms the classical observations, and Homer's animated description rushes into the memory:

'Egyptian Thebes, in whose palaces vast wealth is stored; from each of whose hundred gates issue two hundred warriors, with their horses and chariots.'

"These venerable ruins, probably the most ancient in the world, extend for about three leagues in length along the Nile. East and west they reach to the mountains, a breadth of about two leagues and a half. The river is here about three hundred yards broad. The circumference of the ancient city must therefore have been about twenty-seven miles.

"In sailing up the Nile, the first village you come to within the precincts is Kourna, on the west, where there are few houses, the people living mostly in the caverns. Next is Abuhadjadj, a village, and Karnac, a small district, both on the east. Far the largest portion of the city stood on the eastern side of the river. On the south-west Medinet-Abu marks the extremity of the ruins; for Arment, which is about two leagues to the south, cannot be considered as a part.

"In describing the ruins, we shall begin with the most considerable, which are on the east of the Nile. The chief is the Great Temple, an oblong square building of vast extent, with a double colonnade, one at each extremity. The massy columns and walls are covered with hieroglyphics; a labour truly stupendous. 1. The Great Temple stands in the district called *Karnac*. 2. Next in importance is the temple at *Abulhadjadj*. 3. Numerous ruins, avenues marked with remains of sphinxes, &c. On the west side of the Nile appear, 1. Two colossal figures, apparently of a man and woman, formed of a calcareous stone like the rest of the ruins. 2. Remains of a large temple, with caverns excavated in the rock. 3. The magnificent edifice styled the *palace of Memnon*. Some of the columns are about forty feet high, and about nine and a half in diameter. The columns and walls are covered with hieroglyphics. This stands at *Kourna*. 4. Behind the palace is the passage styled *Biban-el Meluk*, leading up the mountain; at the extremity of this passage, in the sides of the rock are the celebrated caverns known as the sepulchres of the ancient kings."

Though Mr Browne agrees with Pococke and Bruce, that the passage in Homer refers not to the gates of the city, he is yet of opinion, contrary to them, that Thebes had been a walled town. He says, indeed, that some faint remains of its surrounding wall are visible at this day; and he thinks that he discovered the ruins of three of its gates, though he does not affirm this with absolute confidence.

THEODOSIUS, a celebrated mathematician, flourished in the times of Cicero and Pompey; but the time and place of his death are unknown. This Theodosius, the Tripolite, as mentioned by Suidas, is probably the same with Theodosius the philosopher of Bythinia, who, Strabo says, excelled in the mathematical sciences, as also his sons; for the same person might have travelled from the one of those places to the other, and spent part of his life in each of them; like as Hipparchus was called by Strabo the Bythinian, but by Ptolemy and others the Rhodian. B.C.

Theodosius chiefly cultivated that part of geometry which relates to the doctrine of the sphere, concerning which he published three books. The first of these contains 22 propositions; the second, 23; and the third, 14; all demonstrated in the pure geometrical manner of the ancients. Ptolemy made great use of these propositions, as well as all succeeding writers. These books were translated by the Arabians, out of the original Greek, into their own language. From the Arabic the work was again translated into Latin, and printed at Venice. But the Arabic version being very defective, a more complete edition was published, in Greek and Latin, at Paris 1558, by John Pena, Regius Professor of astronomy. And Vitello acquired reputation by translating Theodosius into Latin. This author's works were also commented on and illustrated by Clavius, Heleganius, and Guarinus, and lastly by De Chales, in his Cursus Mathematicus. But that edition of Theodosius's Spherics, which is now most in use, was translated and published by our countryman the learned Dr Barrow,

fow, in the year 1675, illustrated and demonstrated in a new and concise method. By this author's account, Theodosius appears, not only to be a great master in this more difficult part of geometry, but the first considerable author of antiquity who has written on that subject.

Theodosius, too, wrote concerning the Celestial Houses; also of Days and Nights; copies of which, in Greek, were in the King's library at Paris. Of which there was a Latin edition, published by Peter Dasypody, in the year 1572.

THEON, of Alexandria, a celebrated Greek philosopher and mathematician, who flourished in the 4th century, about the year 380, in the time of Theodosius the Great; but the time and manner of his death are unknown. His genius and disposition for the study of philosophy were very early improved by close application to all its branches; so that he acquired such a proficiency in the sciences as to render his name venerable in history, and to procure him the honour of being president of the famous Alexandrian school. One of his pupils was the admirable Hypatia, his daughter, who succeeded him in the presidency of the school; a trust which, like himself, she discharged with the greatest honour and usefulness. See her life, *Encycl.*

The study of Nature led Theon to many just conceptions concerning God, and to many useful reflections in the science of moral philosophy. Hence, it is said, he wrote with great accuracy on Divine Providence. And he seems to have made it his standing rule, to judge the truth of certain principles, or sentiments, from their natural or necessary tendency. Thus, he says, that a full persuasion that the Deity sees every thing we do, is the strongest incentive to virtue; for he insists, that the most profligate have power to refrain their hands, and hold their tongues, when they think they are observed, or overheard, by some person whom they fear or respect. With how much more reason then, says he, should the apprehension and belief, that God sees all things, restrain men from sin, and constantly excite them to their duty? He also represents this belief concerning the Deity as productive of the greatest pleasure imaginable, especially to the virtuous, who might depend with greater confidence on the favour and protection of Providence. For this reason, he recommends nothing so much as meditation on the presence of God: and he recommended it to the civil magistrate as a restraint on such as were profane and wicked, to have the following inscription written, in large characters, at the corner of every street—GOD SEES THEE, O SINNER.

Theon wrote notes and commentaries on some of the ancient mathematicians. He composed also a book, intitled *Progymnasmata*, a rhetorical work, written with great judgment and elegance; in which he criticised on the writings of some illustrious orators and historians; pointing out, with great propriety and judgment, their beauties and imperfections; and laying down proper rules for propriety of style. He recommends conciseness of expression, and perspicuity, as the principal ornaments. This book was printed at Basle in the year 1541; but the best edition is that of Leyden, in 1626, in 8vo.

THEOPHILANTHROPISTS, a sect of deists, who, in September 1796, published at Paris a sort of catechism or directory for social worship, under the title of *Manuel des Theanthrophiles*. This religious breviary found favour: the congregation became numerous; and in the second edition of their manual they assumed the less harsh denomination of *Theophilanthropes, i. e* lovers of God and man. A book of hymns, a liturgy for every decade of the French year, and an homiletical selection of moral lessons, are announced or published, by their unknown synod. Thus they possess a system of pious services adapted to all occasions, which some one of the individuals who attend reads aloud; for they object to the employment of a regular lecturer, in consequence of their hostility to priests.— This novel sect was countenanced by Larevelliere Lepaux, one of the Directory, and, soon after its formation, opened temples of its own in Dijon, and in other provincial towns They had declamations, in the spirit of sermons, which abounded with such phrases as *l'eternal geometre*, and the like, and which have long since been familiar to those who frequent the lodges of free masonry. Whether the sect now exists, or fell at the last revolution which annihilated the directory, we have not learned; but a translation of its *Manuel* into English, for the use, we suppose, of our Jacobins, was made so early as the year 1797. From this contemptible performance, we learn that the creed of the Theophilanthropists is comprised in the four following propositions:

The Theophilanthropists believe in the existence of God, and the immortality of the soul.

The spectacle of the universe attests the existence of the First Being.

The faculty which we possess of thinking, assures us, that we have, within ourselves, a principle which is superior to matter, and which survives the dissolution of the body.

The existence of God, and the immortality of the soul, do not need long demonstrations; they are sentimental truths, which every one may find written in his heart, if he consult it with sincerity.

Thus a sort of religious instinct is set up as the sole foundation of piety, which every one has as much right to disavow as another to assert; and the obligations of which, therefore, can in no way be shewn to be incumbent on those to whom this novel illumination is not vouchsafed. Society, under such a system, gains no means of influencing the conduct of refractory members.

The morality of the Theophilanthropists is founded on one single precept: *Worship God, cherish your kind, render yourselves useful to your country!*

Among the duties comprehended under the denomination of cherishing our kind, we find that of *not lending for usury:* the others are chiefly extracted from the gospels, and do not interfere with the province of the civil magistrate. The question of monogamy is not discussed.

Among the duties to our country are placed those of fighting in its defence, and of paying the taxes. It was certainly prudent in the statesman to slide these duties into the catalogue of his established maxims of morality; and he ran thereby little risk of provoking heretical animadversions on his creed in France.

The following inscriptions are ordered to be placed above the altars in the several temples or synagogues of the Theophilanthropists; but for what reason altars are admitted into such synagogues we are not informed:

Theophilanthropists. Theophilus.

First inscription, "We believe in the Existence of God, in the immortality of the soul."

Second inscription. "Worship God, cherish your kind, render yourselves useful to the country."

Third inscription, "Good is every thing which tends to the preservation or the perfection of man.—Evil is every thing which tends to destroy or to deteriorate him."

Fourth inscription, "Children, honour your fathers and mothers. Obey them with affection. Comfort their old age.—Fathers and mothers, instruct your children."

Fifth inscription, "Wives, regard in your husbands the chiefs of your houses.—Husbands, love your wives, and render yourselves reciprocally happy."

This pentalogue is chiefly objectionable on account of the vague drift of the fifth commandment: the whole has too general a turn for obvious practical application. The introduction of ceremonies of sculpture, of painting, and of engraving, is forbidden. If poetry and music may concur to render the worship impressive, why not the other fine arts? The fine arts have never illustrated a country which excluded them from the public temples. Are they to be extinguished in France by Theophilanthropic iconoclasts?

At p. 78. of the Manuel, this surprising maxim occurs: *Avoid innovations!* A sect fifteen months old grown as testy as the church of Rome! They acknowledge, that perhaps better inscriptions may be found; yet they forbid the exchange. They prefer *mumpsimus* to the *sumpsimus* of genuine Christianity!

THEOPHILUS, a writer and bishop of the primitive church, was educated a Heathen, and afterwards converted to Christianity. Some have imagined that he is the person to whom St Luke dedicates the Acts of the Apostles; but they are grossly mistaken; for this Theophilus was so far from being contemporary with St Luke and the apostles, that he was not ordained bishop of Antioch till *anno* 170; and he governed this church twelve or thirteen years. He was a vigorous opposer of certain heretics of his time, and composed a great number of works; all of which are lost, except three books to Autolycus, a learned Heathen of his acquaintance, who had undertaken to vindicate his own religion against that of the Christians. The first book is properly a discourse between him and Autolycus, in answer to what this Heathen had said against Christianity. The second is to convince him of the falsehood of his own, and the truth of the Christian religion. In the third, after having proved that the writings of the Heathens are full of absurdities and contradictions, he vindicates the doctrine and the lives of the Christians from those false and scandalous imputations which were then brought against them. Lastly, at the end of his work, he adds an historical chronology from the beginning of the world to his own time, to prove that the history of Moses is at once the most ancient and the truest; and it appears from this little epitome, how well this author was acquainted with profane history. These three books are filled with a great variety of curious disquisitions concerning the opinions of the poets and philosophers, and there are but few things in them relating immediately to the doctrines of the Christian religion. Not that Theophilus was ignorant of these doctrines, but, having composed his works for the conversion of a Pagan, he insisted rather on the external evidence or proofs from without, as better adapted, in his opinion, to the purpose. His style is elegant, and the turn of his thoughts very agreeable; and this little specimen is sufficient to shew that he was indeed a very eloquent man.

. Dict.

The piece is intitled, in the Greek manuscripts, "The books of Theophilus to Autolycus, concerning the Faith of the Christians, against the malicious detractors of their religion." They were published, with a Latin version, by Conradus Gesner, at Zurich, in 1546. They were afterwards subjoined to Justin Martyr's works, printed at Paris in 1615 and 1636; then published at Oxford, 1684, in 12mo, under the inspection of Dr Fell; and, lastly, by Jo Christ. Wolfius, at Hamburgh, 1723, in 8vo.

It is remarkable, that this patriarch of Antioch was the first who applied the term *Trinity* to express the Three Persons in the Godhead.

Therapeutæ.

THERAPEUTÆ, so called from the extraordinary purity of their religious worship, were a Jewish sect, who, with a kind of religious phrenzy, placed their whole felicity in the contemplation of the Divine nature. Detaching themselves wholly from secular affairs, they transferred their property to their relations or friends, and withdrew into solitary places, where they devoted themselves to a holy life. The principal society of this kind was formed near Alexandria, where they lived, not far from each other, in separate cottages, each of which had its own sacred apartment, to which the inhabitant retired for the purposes of devotion. After their morning prayers, they spent the day in studying the law and the prophets, endeavouring, by the help of the commentaries of their ancestors, to discover some allegorical meaning in every part. Besides this, they entertained themselves with composing sacred hymns in various kinds of metre. Six days of the week were, in this manner, passed in solitude. On the seventh day they met, clothed in a decent habit, in a public assembly; where, taking their places according to their age, they sat, with the right hand between the breast and the chin, and the left at the side. Then some one of the elders, stepping forth into the middle of the assembly, discoursed, with a grave countenance and a calm of tone voice, on the doctrines of the sect; the audience, in the mean time, remaining in perfect silence, and occasionally expressing their attention and approbation by a nod. The chapel where they met was divided into two apartments; one for the men, the other for the women. So strict a regard was paid to silence in these assemblies, that no one was permitted to whisper, or even to breathe aloud; but when the discourse was finished, if the question which had been proposed for solution had been treated to the satisfaction of the audience, they expressed their approbation by a murmur of applause. Then the speaker, rising, sung a hymn of praise to God, in the last verse of w[illegible] whole assembly joined. On great festivals, the meeting was closed with a vigil, in which sacred music was performed, accompanyed with solemn dancing: and these vigils were continued till morning, when the assembly, after a morning prayer, in which their faces were directed towards the rising sun, was broken up. So abstemious were these ascetics, that they commonly ate nothing before the setting sun, and often fasted two or three

three days. They abstained from wine, and their ordinary food was bread and herbs.

Much dispute has arisen among the learned concerning this sect. Some have imagined them to have been Judaizing Gentiles; but Philo supposes them to be Jews, by speaking of them as a branch of the sect of Essenes, and expressly classes them among the followers of Moses. Others have maintained, that the Therapeutæ were an Alexandrian sect of Jewish converts to the Christian faith, who devoted themselves to a monastic life. But this is impossible; for Philo, who wrote before Christianity appeared in Egypt, speaks of this as an established sect. From comparing Philo's account of this sect with the state of philosophy in the country where it flourished, we conclude, that the Therapeutæ were a body of Jewish fanatics, who suffered themselves to be drawn aside from the simplicity of their ancient religion by the example of the Egyptians and Pythagoreans. How long this sect continued is uncertain; but it is not improbable that, after the appearance of Christianity in Egypt, it soon became extinct.

THERMOMETRIC SPECTRUM, is a name given to the space in which a thermometer may be placed, so that it shall be affected by the sun's rays refracted by a prism. It is, in part, the same with the PRISMATIC SPECTRUM, which exhibits the different colours produced by the solar light.

The philosophical instrument now called a *thermometer*, was first named THERMOSCOPE; and was prized by the naturalist, because it gave him indications of the presence and agency of fire in many cases where our sensation of warmth or heat was unable to discover it. It was not long before it was observed that it also affords us measures of the changes which take place either in the quantity or the activity of the cause of heat, and of many other important pheunomena usually accompanied by heat. They were then called *thermometers*. But in both of these offices, it is still a doubt whether it indicates and measures any real substance, a being *sui generis*, to which we may give the name *fire*, *phlogiston*, *caloric*, *heat*, or any other; or only indicates and measures certain states or conditions, in which all bodies may be found, without the addition or abstraction of any material substance.

We think that this question has a greater chance now of being decided than in any former time, in consequence of a recent and very important discovery made by that unwearied observer of the works of God, the celebrated Dr Herschel. Being greatly incommoded when looking at the sun, by the great heats produced in the eye-pieces of his telescopes, he thought that the laws of refraction enabled him to diminish them by a proper construction of his eye-pieces. He began his attempts like a philosopher, by examining the heat produced in the various parts of the prismatic spectrum. Comparing the gradation of heat with that of illumination, he found that they did not, by any means, follow the same law. The illumination increased gradually from the violet end of the spectrum, where it was exceedingly faint, to the boundary of the green and yellow, where it was the most remarkable; and after this, it decreased as the illuminated object approached the red extremity of the spectrum. But the calorific power of the refracted light increased all the way from the extreme violet to the extreme red; and its last augmentations were considerable, and therefore unlike the usual approaches of a quantity to its maximum state. This made him think of placing the thermometer a little way beyond the extremity of the visible spectrum. To his great astonishment, he found that the thermometer was more affected there than in the hottest part of the *illuminated* spectrum. Exposing the thermometer at various distances beyond the extreme red, but in the plane of refraction, he found that it was most strongly affected when placed beyond that extremity, about one-fifth of the whole length of the spectrum; from thence the calorific influence of the sun gradually diminished, but was still very considerable, at a distance from the extreme red equal to three fifths of the length of the luminous spectrum. These first suggested modes of trial appeared to Dr Herschel to be too rude to intitle him to say that the warming influence did not extend still farther. Indeed the instrument scarcely performed the part of a thermometer, but merely that of an indicator of heat, or a thermoscope.

Here is a very new, and wonderful, and important, piece of information. We apprehend that all the philosophers of Europe, as well as the unlearned of all nations, believe that the *warming* influence of the sun, and of other luminous bodies, is conjoined with their power of *illumination*. Most of the philosophers admitted the emission of a matter called *light*, projected from the shining body, and moving with astonishing velocity, in those lines which the mathematicians called *rays*, because they diverged from the shining point, as the *radii* or spokes of a wheel diverge from the nave. This notion seems to be the simple suggestion of Nature; and it also seems to be the opinion entertained by Sir Isaac Newton. His demonstration of the laws of reflection and refraction proceeds on this supposition alone, and the particles of light are held by him to be affected by accelerating and deflecting forces, in the same way as a stone thrown from the hand is affected by gravity. Huyghens, indeed, Dr Hooke, and Euler, imagined that vision and illumination were effected in the same way that hearing, and resonance, and echo, are effected—that there is no matter projected from the shining body; but that we are surrounded by an elastic fluid, which is thrown into vibrations by certain tremors of the visible object—and that those vibrations of this fluid affect our eye in the same way as the undulation of elastic air, produced by the tremors of a string or a bell, affect our ear. According to these philosophers, a ray of vision is merely the line which passes through all these undulations at right angles.

These two opinions still divide the mathematical philosophers of Europe; but the majority, and particularly the most eminent for mathematical and mechanical science, are (with the exception of Huyghens and Euler) on the side of the vulgar. This opinion has been greatly strengthened of late years by the discoveries in chemistry. The influence of light on the growth of plants, the total want of aromatic oils in such as grow in the dark, and their formation and appearance in the very same plant, along with the green colour, as soon as the plant is placed in the light (even that of open day without sunshine, or in the light of a candle), is a strong indication of some substance being obtained from the light, absorbed by the plant, and combined with its other ingredients. The same conclusion is drawn from the

the effects of the sun's light on vegetable colours, on the nitric and nitrous acids, on manganese, on the calces or oxyds of metals, and numberless other instances, which all concur in rendering it almost unquestionable that the sun's rays, and those of other shining bodies, may be, and daily are, combined with the other substances of which bodies are composed, and may be again separated from them. And, should any doubts remain, it would seem that the theory of combustion, first conceived and imperfectly published by Dr Hooke in his *Micrography*, p. 103. and in his *Lampas*, p. 1. &c. adopted by Mayow (see HOOKE and MAYOW in this *Suppl.*), forgotten, and lately revived and confirmed by Mr Lavoisier, removes them entirely. In the beautiful and well-contrived experiments of the last gentleman, the light, accompanied by its heat which had been absorbed in the process of growth or other natural operations, re-appeared in their primitive form, and might again be absorbed and made to undergo the same round of changes.

Scheele, not inferior to Newton in caution, patience, and accuracy, and attentive to every thing that occurred in his experiments, discovered the separability of the illuminating and the warming influences of shining bodies. He remarked, that a plate of glass, the most colourless and pellucid that can be procured, when suddenly interposed between a glowing fire and the face, instantly cuts off the warming power of the fire, without causing any sensible diminution of its brilliancy. He followed this discovery into many obvious consequences, and found them all fully confirmed by observation and experiment. The writer of this article, immediately on hearing of Scheele's experiments, repeated them with complete success: but he found, that when the glass plate had acquired the highest temperature which it could acquire in that situation, it did not any longer intercept the heat, or at least in a very small and almost insensible degree. It seemed to absorb the heat, till saturated, without absorbing any considerable portion of the light.

This separability of heat from light does not seem to have met with the attention it deserved. Dr Scheele's untenable theories on these subjects turned away the attention of the chemists from this discovery, and the mathematical philosophers seem not to have heard of it at all. The late Dr Hutton of Edinburgh was more sensible of its importance; and in his last endeavours to support the falling cause of phlogiston, makes frequent allusions to it. But in his attempts to explain the curious observations of Messrs Saussure and Pictet, in which there are unquestionable appearances of radiated heat, he reasons so unconsequentially, that few readers proceed farther, so as to notice several observations of facts where the illuminating and warming influences are plainly separated. In all these instances, however, Dr Hutton considers the invisible rays as light, but not as heat; maintaining that they are invisible, or do not render bodies visible, only because our eyes are insensible to their feeble action.

It was reserved for Dr Herschel to put this matter beyond dispute by these valuable experiments. For did the invisibility of any of the light beyond the extreme red of the prismatic spectrum arise from the insensibility of our organs, the spectrum would gradually fade away beyond the red; but it ceases abruptly. These thoughts could not escape this attentive observer. He therefore examined more particularly those invisible rays, causing them to be reflected by mirrors, and refracted through lenses; and, in short, he subjected them to all the subsequent treatments which Newton applied to the colouring rays. He found them retain their specific refrangibilities and reflexibilities with as much uniformity and obstinacy as Newton had observed in the colour-making rays. They were made to pass through lenses while the illuminating rays were intercepted by an opaque body, and the invisible rays were then collected into a focus. They were reflected, both by the anterior and posterior surfaces of transparent bodies. In all these trials they retained their power of expanding the liquor of a thermometer, and exciting the sensation of heat

Thermometric.

These trials were not confined to the solar light or the solar rays: They were also made on the emanations from a candle, from an open fire, and from red hot iron; then they were made with bodies not hot enough to shine; with the heat of a common stove, and the heat from iron which was not visible in the dark. The event was the same in all; and it was clearly proved that heat, or the cause of heat, is as susceptible of radiation as light is; and that this radiation is performed in both according to the same laws.

We look with impatience for the subsequent experiments of this celebrated philosopher on this subject; for we consider them as of the greatest and most extensive importance for explaining the operations of Nature. We see, with indisputable evidence, that there are rays from the sun, and other bodies, which do not illuminate. It does not follow, however, that there are rays which do not warm; for the thermometer was affected in every part of the coloured spectrum. Dr Herschel seems to think that the power of affecting the organ of sight depends on the particular degrees of mechanical momentum which are indicated by the different degrees of refrangibility. We confess that we think it unlikely that such a power should terminate abruptly. We do not observe this in analogous phenomena: the evanescence of our sensations of sound, of musical pitch, of heat, &c. are all gradual. We think it more likely that illuminating and warming are specific effects of different things. We should have entertained this opinion independent of all other experience; and we think it strongly confirmed by the experiments of Dr Scheele already mentioned. We are disposed therefore to believe that there are rays which illuminate, but which do not warm; and rays which warm without illuminating. We have experiments in prospect, by which we hope to put this to the test.

These experiments of Dr Herschel afford another good argument for the common opinion concerning light, namely, that *it is a matter emitted from the shining body*, and not merely the undulations of an elastic medium; for if it were undulation, then, since there is heat in the yellow light, it would follow that a certain frequency of undulation produces both the sensation of heat and the sensation of a yellow colour. In this case they should be inseparable.

This follows, in the strictest manner, from the principles or assumptions adopted by Euler in his mechanical theory of undulations. The chromatic differences in the rays of light are affirmed to arise entirely from the

the different frequencies of the ætherial undulations; and he endeavours to shew that these differences in frequency produce a difference in refrangibility. It is evident that this reasoning is equally conclusive with respect to the calorific or heating power of the rays. The light and the heat are both undulations: these differ only in frequency; and this frequency is indicated (according to Euler) by the refrangibility. There is a certain frequency therefore which excites the sensation of yellow. The same frequency, indicated by the same refrangibility, produces heat; therefore the frequency which produces this degree of heat also produces the sensation of yellow. We must not say that the momentum of the undulation may produce heat, but is insufficient for the production of light, as a string may vibrate too [illegible] for being heard: for we see, by Dr Herschel's experiments, that, with a momentum sufficient for making the most brilliant spectrum, there are rays (and those which have the greatest momentum) which produce heat, and yet are invisible.

It does not follow, from any of Dr Herschel's experiments, that the rays emitted by iron, which is not hot enough to shine in a dark room, have *all* the different degrees of refrangibility observed by him. Perhaps none of them would fall on the chromatic spectrum. We think, however, that this is not probable. It may be tried by collecting them to a focus by a lense, intercepting, however, all those which are less refrangible than the red making rays. We trust that the thermometer in the focus will still be affected.

This is but a very imperfect account of this important discovery: but we thought that it would be highly interesting to our readers. The press was employed on this very sheet when we received the information from a friend, who had seen Dr Herschel's Dissertation, which will appear in the first volume published by the Royal Society. We trust that the ingenious author will soon follow it up with the investigation of the subject in all its consequences.

We hope that he will examine what will result from mixing some of the invisible rays with some of the coloured ones. We know that the yellow and the blue, when mixed, produce the sensation of green. Perhaps the invisible rays may also change the appearance. We do not, however, expect this.

We also hope that Dr Herschel will examine whether the invisible rays of the sun produce any effect on vegetable colours; whether they blacken the calces of silver and bismuth, luna cornea, and decompose the nitrous and the oxygenated muriatic acid, &c. &c. We should thus get more insight into the nature of caloric and of combustion. Combustion may perhaps be restored to its rank in the phenomena of Nature, and no longer be sunk in the general gulph of oxygenation, and thus obliterated from the memory of chemists. It is perhaps the most remarkable phenomenon of material Nature; and *fire* and burning will never go out of the language of plain men. Fire, and all its concomitants, have, in all times, been considered as even the *chief* objects of chemical attention; and an unlearned person will stare, when a chemist tells him that there is no such thing, and that what he calls the burning of a piece of coal is only the making it sour. He will perhaps smile; but it will not be a smile of assent.

It was one darling object of the Revolutionary Committee of Chemists, assembled at Paris in 1787, to banish from our minds, *by means of a new language*, all remembrance of any thing which we did not derive from the philosophers of France. We think ourselves in a condition to prove this by letters to this country from the scene of action; in which the expected victory is spoken of in terms of exultation, and with so little restraint, that the writer forgets that it is Dr Black whom he is informing that *l'air fixe* and *la pauvre phlogistique* will soon be forgotten; and yet the writer was a gentleman of uncommon modesty and worth, and sincerely attached to Dr Black. We give this as a remarkable instance of the *esprit de corps*, and of the nature and towering ambition of that nation. From this they have not swerved; and they hope to gain this summit of scientific dominion in the same way as *the same philosophers* hope to banish Christianity by means of their new kalendar. It may, however, turn out that both Dr Hooke and Mr Lavoisier are mistaken, when they make the oxygen gas the sole source of both the light and the heat which accompany combustion. One of them may perhaps be furnished by the body which all, except the new philosophers, call combustible.

Thermometric

The objections which may be made to the theory of Huyghens and Euler, on the acknowledged principles of mechanics, appear to us unanswerable. Euler has never attempted to answer those taken from the different dispersing powers of different substances. The objections made to the Newtonian, or vulgar theory of emission, are not such as imply absurdity; they are only difficulties. The chief of them, *viz.* the sameness of velocity in all lights whatever, is of this kind. It is merely an improbability. But the objections to the theory of undulation, deduced from the chemical effects of light, are not less strong than those deduced from mechanical principles. It is quite inconceivable that the undulation of a medium, which pervades all bodies, shall produce aromatic oils in some, a green fæcula in others, shall change sulphuric acid into sulphur, &c. &c. No effects are produced by the undulations of air, or the tremors of elastic bodies, which have the most distant analogy or resemblance to these.

That the sun and other shining bodies emit the matter of light and heat, seems therefore to merit the general reception which it meets with from the philosophers. But even of this class there are differences in opinion. Some imagine that light only is emitted, and that the heat which we feel is occasioned by the action of the luminous rays on our atmosphere, or on the ground. Were the sun's calorific rays as dense at the surface of the sun as his luminous rays are, the heat there must exceed (say they) all that we can form any conception of. Yet we see, that when the nucleus of the sun is laid bare by some natural operation, which, like a volcanic explosion, throws aside the luminous ocean which covers it to a prodigious depth, the naked parts of this nucleus are black. Therefore the intense heat in that place is not able to make it shining hot, as it does in all our experiments with intense heats, giving a dazzling glare. This is thought highly improbable; and it is therefore supposed that there is, primitively, no heat in the sun's rays, but that they act on our air, or other terrestrial matter, combining with it, and disengaging heat from it, or producing that particular state and condition which we call *heat*.

We think that Dr Herschel's discovery militates strongly and irresistibly against this opinion; and shews, that

that whatever reason we have for saying that the sun's rays bring light from the sun we have the same authority for saying, that they bring heat, fire, caloric, phlogiston, or by whatever other name we choose to distinguish the cause of warmth, expansion, liquefaction, ebullition, &c.

We must either say that light and heat are not substances of a peculiar kind, susceptible of union with the other ingredients of bodies, but merely a state of undulation of an elastic medium, as sound is the undulation of air; or we must say that the sun's rays contain light and heat, in a detached state, fit for appearing in their simplest form, producing illumination and expansion, and for uniting chemically with other matter. Whichever of these opinions we adopt, it is pretty clear that all attempts to discover a difference in the weight of hot and cold bodies may be given over. In the first case, it is self-evident; in the second, we have abundant evidence, that if light and heat, being gravitating matter, like all other bodies, were added to, or abstracted from bodies, in sufficient quantity to be sensibly heavy, the rays of the sun, or even the light of a candle, would occasion instant destruction by its mere momentum; since every particle of radiated light and heat moves at the rate of 200,000 miles in a second.

This discovery of Dr Herschel's adds greatly to the probability of the opinion which we expressed on another occasion, that the forces or powers of natural substances, which are the immediate causes of the chemical phenomena, are no way different from the mechanical forces which render bodies heavy, coherent, elastic, expansive, &c.; in short, that they are what we call *accelerating forces*. We deduced this from the fact, that mechanical force can be opposed to them, so as to prevent their action in circumstances where it would otherwise certainly take place. Thus, by external pressure, we can prevent that union of water and caloric which would convert it into elastic steam. We can even disunite them again, when steam is already produced, by forcibly condensing it into a smaller space. Now, the refraction and reflection of heat are performed according to the same precise laws which we observe in the refraction and reflection of light; and Sir Isaac Newton has demonstrated that those phenomena arise from the action of accelerating forces, whose direction is perpendicular to the acting surfaces. The matter of heat, therefore, is like other matter in its mechanical properties; and, in the motion of refraction, it is acted on and deflected, just as a projectile is acted on and deflected by gravity. It continues in motion till its velocity and direction are changed by deflecting forces, exerted by the particles of the transparent medium or the reflecting surface. It would take up too much room, but it is a very easy process, to demonstrate that this regular refraction of heat is altogether incompatible with the usually supposed notion of caloric; namely, that it is an expansive fluid like air, but incomparably more elastic: from which property very plausible explanations have been given of the elasticity of gases, steams, and such like fluids. Every intelligent mechanician will be sensible, that all this sort of chemical science falls to the ground, when it is proved, by exhibition of the fact, that radiated heat is refracted in the same way with radiated light. We must look for the explanation of the immense explosive force of fulminating silver, gold, &c. in some very different principles from those which are now in vogue. We apprehend, too, that the very phenomenon of this refraction gives indication of forces which are sufficiently powerful for this explanation: For when we reflect on the astonishing velocity of the ray of heat; on the minute space along which it is deflected, and consequently the time of this action, minute beyond all imagination; and when we compare these circumstances with the deflection produced by gravity in the motion of a projectile — it is evident that the deflecting force of refraction must exceed the greatest force that we have any knowledge of, in a greater proportion than the weight of Mount Ætna exceeds that of a particle of sand. We would desire Mr de la Place to suspend his hopes of establishing universal fatalism, till he can reconcile these phenomena with his fundamental " *that all forces which are diffused from a single point, necessarily and essentially diminish in the inverse duplicate ratio of the distances.*" Till he can do this, he had better still allow, with Newton, that the selection of the duplicate ratio for the action of gravity (by which alone the solar system can be rendered permanent and orderly) is a mark of wisdom and benevolence. We would advise him to reconcile his mind to this; and perhaps, like the modest and admiring Newton, he may, in good time, find comfort in the thought.

It is also highly worthy of remark, that this refracting force, almost immense, which is so plainly exerted between the particles of bodies and light, when considered as of the same kind with those that produce chemical union, appears abundantly sufficient for explaining some of the most wonderful phenomena of chemistry; such as the prodigious elasticity of steam, of gunpowder, and the still more astonishing explosion of fulminating gold and silver. Some of the phenomena of deflected light are produced by these optical forces acting at distances sufficiently great to admit of measurement; as in the Newtonian observations on the passage of light near the edges of opaque bodies. These deflections enable us to compare the deflecting forces with gravity. The *refracting* force, however, is vastly greater than even this, as may be seen by the greater deflection which is produced by it; and, being exerted along a space incomparably smaller, it must be greater still. Here, then, are forces fully adequate to the phenomena of fulmination. And we would again desire Mr De la Place to remark that, although these exploding forces are irresistible, their action seems to vanish entirely beyond the limits of mathematical contact. This is plain from the fact, that those explosions do not project the fragments to great distances. This is remarkably the case in all the most eminent of them. Common or nitric gunpowder is perhaps the only great exception. This particular circumstance will surely suggest to this eminent analyst the *inverse triplicate* ratio of the distance as more likely to explain the phenomena than his favourite law.

We trust that our readers will not be displeased with this short sketch of Dr Herschel's discovery, and the few reflections which it naturally suggested to our minds. We shall not be greatly surprised, although it should produce a sort of counter revolution in chemical science, in consequence of new conceptions which it may give us of the union of bodies with light and heat. The phenomena of the vegetable and animal economy

Thevenot, Thomas.

that they are susceptible of combination with other substances besides the basis of vital air. Whatever changes this may produce in the great revolution which has already taken place in chemical science, they will (in our opinion) be favourable to true philosophy; because Dr Herschel's discovery co-operates with other arguments of sound mathematical reasoning, to overturn that principle on which De la Place hopes to found his atheistical doctrine of fate and necessity. It contributes therefore to restore to the face of Nature that smiling feature of providential WISDOM which Newton had the honour of exhibiting to the view of rational men. The sun is the source of light and genial warmth to a vast system, which is held together, in almost eternal order and beauty, by a law of attraction selected by Infinite Wisdom, as the only one adequate to this magnificent purpose.

THEVENOT (Melchisedec), librarian to the king of France, and a celebrated writer of travels, was born at Paris in 1621, and had scarcely gone through his academical studies, when he discovered a strong passion for visiting foreign countries. At first he saw only part of Europe; but then he took great care to procure very particular informations and memoirs from those who had travelled over other parts of the globe, and out of those composed his "Voyages and Travels."—He laid down, among other things, some rules, together with the invention of an instrument, for the better finding out of the longitude, and the declination of the needle; and some have thought that these are the best things in his works, since travels, related at second-hand, can never be thought of any great authority or moment; not but Thevenot travelled enough to relate some things upon his own knowledge. Another passion in him, equally strong with that for travelling, was to collect scarce books in all sciences, especially in philosophy, mathematics, and history; and in this he may be said to have spent his whole life. When he had the care of the King's library, though it was one of the best furnished in Europe, he found 2000 volumes wanting in it which he had in his own. Besides printed books, he bought a great many manuscripts in French, English, Spanish, Italian, Latin, Greek, Hebrew, Syriac, Arabic, Turkish, and Persic. The marbles presented to him by Mr Nointel, at his return from his embassy to Constantinople, upon which there are bas-reliefs and inscriptions almost 2000 years old, may be reckoned among the curiosities of his library. He spent most of his time among his books, without aiming at any post of figure or profit; he had, however, two honourable employments; for he assisted at a conclave held after the death of Pope Innocent X and was the French king's envoy at Genoa. He was attacked with what is called a slow fever in 1692, and died October the same year, at the age of 71. According to the account given, he managed himself very improperly in this illness; for he diminished his strength by abstinence, while he should have increased it with hearty food and generous wines, which were yet the more necessary on account of his great age.—Thevenot's Travels into the Levant, &c. were published in English in the year 1687, folio; they had been published in French at Paris 1663, folio. He wrote also "L'Art de Nager," the Art of Swimming, 12mo, 1696.

THOMAS (Christian) was born at Leipsic 1655, and was well educated, first under his father, and afterwards in the Leipsic university. At first he acquiesced in the established doctrines of the schools; but upon reading Puffendorf's "Apology for rejecting the Scholastic Principles of Morals and Law," light suddenly burst upon his mind, and he determined to renounce all implicit deference to ancient dogmas. He read lectures upon the subject of Natural Law, first from the text of Grotius, and afterwards from that of Puffendorf, freely exercising his own judgment, and, where he saw reason, advancing new opinions. Whilst his father was living, paternal prudence and moderation restrained the natural vehemence and acrimony of the young man's temper, which was too apt to break out, even in his public lectures. But when he was left to himself, the boldness with which he advanced unpopular tenets, and the severity with which he dealt out his satirical censures, soon brought upon him the violent resentment of theologians and professors.

An "Introduction to Puffendorf," which Thomas published in the year 1687, wherein he deduced the obligation of morality from natural principles, occasioned great offence. The following year he became still more unpopular, by opening a monthly literary journal, which he intitled "Free Thoughts, or Monthly Dialogues on various Books, chiefly new;" in which he attacked many of his contemporaries with great severity. The raillery of this satirical work was too provoking to be endured: complaints were lodged before the ecclesiastical court of Dresden; the bookseller was called upon to give up the author; and it was only through the interest of the Mareschal that Thomas escaped punishment. The title of the work was now changed; but its spirit remained. A humorous and satirical life of Aristotle, and several other sarcastic papers, kept alive the flame of resentment, till at length it again burst forth, on a charge brought against him before the same court by the clergy of Leipsic, for contempt of religion; but he defended himself with such ability, that none of his adversaries chose to reply, and the matter was dropped.

A satirical review, which he wrote, of a treatise "On the Divine Right of Kings," published by a Danish divine; "A Defence of the Sect of the Pietists," and other eccentric and satirical publications, at last inflamed the resentment of the clergy against Thomas to such a degree, that he was threatened with imprisonment. To escape the storm which thickened about him, he entreated permission from the Elector of Brandenburg, in whose court he had several friends, that he might read private lectures in the city of Hall. This indulgence being obtained, Thomas became a voluntary exile from Leipsic. After a short interval, he was appointed public professor of jurisprudence, first in Berlin, and afterwards at Hall. In these situations, he found himself at full liberty to indulge his satirical humour, and to engage in the controversies of the times: and as long as he lived, he continued to make use of this liberty in a manner which subjected him to much odium.' At the same time, he persevered in his endeavours to correct and subdue the prejudices of mankind, and to improve the state of philosophy. He died at Hall in the year 1728.

Besides the satirical journal already mentioned, Thomas wrote several treatises on logic, morals, and jurisprudence; in which he advanced many dogmas contra-

ry

Thomas, Thornton.

ry to received opinions. In his writings on physics, he leaves the ground of experiment and rational investigation, and appears among the mystics. His later pieces are in many particulars inconsistent with the former.—His principal philosophical works are, "An Introduction to Aulic Philosophy, or Outlines of the Art of Thinking and Reasoning;" "Introduction to Rational Philosophy;" "A Logical Praxis;" "Introduction to Moral Philosophy;" "A Cure for Irregular Passions, and the Doctrine of Self-Knowledge;" "The new Art of discovering the secret Thoughts of Men;" "Divine Jurisprudence;" "Foundations of the Law of Nature and Nations;" "Dissertation on the Crime of Magic;" "Essay on the Nature and Essence of Spirit, or Principles of Natural and Moral Science;" "History of Wisdom and Folly."

From the specimen given by Dr Enfield of his more peculiar tenets (for we have read none of his books), Thomas appears to have been a man of wonderful inconsistency in his opinions; teaching on one subject rational piety and true science, and on another absurdity and atheism. "No other rule (he says) is necessary in reasoning, than that of following the natural order of investigation; beginning with those things which are best known, and proceeding, by easy steps, to those which are more difficult." This is perfectly consistent with the foundation of the Baconian logic; and is indeed the only foundation upon which a system of science can possibly be built. Yet could the man, who professes to proceed from a principle so well established, gravely advance, as conclusions of science, the following absurdities: "Perception is a passive affection, produced by some external object, either in the intellectual sense, or in the inclination of the will. God is not perceived by the intellectual sense, but by the inclination of the will: for creatures affect the brain; but God, the heart. All creatures are in God: nothing is exterior to him. Creation is extension produced from nothing by the divine power. Creatures are of two kinds, passive and active; the former is matter, the latter spirit. Matter is dark and cold, and capable of being acted upon by spirit, which is light, warm, and active. Spirit may subsist without matter, but desires a union with it. All bodies consist of matter and spirit, and have therefore some kind of life. Spirit attracts spirit, and thus sensibly operates upon matter united to spirit. This attraction in man is called *love*; in other bodies, *sympathy*. A finite spirit may be considered as a limited sphere, in which rays, luminous, warm, and active, flow from a centre. Spirit is the region of the body to which it is united. The region of finite spirits is God. The human soul is a ray from the divine nature; whence it desires union with God, who is love. Since the essence of spirit consists in action, and of body in passion, spirit may exist without thought: of this kind are light, ether, and other active principles in nature." Fortunately, this jargon is as unintelligible as the categories of Kant, and the blasphemies of Spinoza; for an account of which, the reader is referred to *Critical* PHILOSOPHY in this *Suppl.* and to SPINOZA in the *Encycl.*

Biographical Dictionary

THORNTON (Bonnel), a modern poet, the intimate friend of Lloyd and Colman, and justly classed with them in point of talents, was born in Maiden-lane, London, in the year 1724. He was the son of an apothecary; and being educated at Westminster school, was elected to Christ Church, Oxford, in the year 1743. He was thus eight years senior to Colman, who was elected off in 1751. The first publication in which he was concerned was, "The Student, or Oxford and Cambridge Miscellany," which appeared in monthly numbers; and was collected in two volumes 8vo, in 1748. Smart was the chief conductor of the work; but Thornton, and other wits of both universities, assisted in it. He took his degree of master of arts in 1750; and as his father wished him to make physic his profession, he took the degree of bachelor of that faculty in 1754. In the same year he undertook the periodical paper called *The Connoisseur*, in conjunction with Colman, which they continued weekly to the 30th of September 1756. In the concluding paper, the different ages and pursuits of the two authors are thus jocularly pointed out, in the description of the double author, Mr Town. "Mr Town is a fair, black, middle-sized, very short man. He wears his own hair and a periwig. He is about thirty years of age (literally thirty two), and not more than four-and-twenty. He is a student of the law and a bachelor of physic. He was bred at the university of Oxford, where, having taken no less than three degrees, he looks down on many learned professors as his inferiors: yet having been there but little longer than to take the first degree of bachelor of arts, it has more than once happened that the censor-general of all England has been reprimanded by the censor of his college, for neglecting to furnish the usual essay, or, in the collegiate phrase, the theme of the week." Engaged in pursuits of this kind, Bonnel Thornton did not very closely follow the profession to which his father destined him, but lived rather a literary life, employing his pen on various subjects. To the daily paper called the *Public Advertiser*, then in high reputation, he was a frequent contributor; and he once had it in contemplation to treat with Mr Rich for the patent of Covent Garden theatre. In 1764, Mr Thornton married Miss Sylvia Brathwaite, youngest daughter of Colonel Brathwaite, who had been governor of a fort in Africa. In 1766, encouraged, as he says himself, by the success of his friend Colman's Terence, he published two volumes of a translation of Plautus in blank verse; proposing to complete the whole if that specimen should be approved. These volumes contained seven plays, of which the *Captive* was translated by Mr Warner, who afterwards completed all that Thornton had left unfinished; and the *Mercator* by Mr Colman. The remaining five are, the *Amphitryon*, *Miles Gloriosus*, *Trinummus*, *Aulularia*, *Rudens*. Some parts of the remaining plays which Thornton had translated are preserved by his continuator. There can be no doubt that this is the best way of translating the old comedies, and that Thornton was well qualified for the task; but the work has never been in high favour with the public. Yet Warburton said of it, that "he never read so just a translation, in so pure and elegant a style." Thornton published in 1767, *The Battle of the Wigs*, as an additional canto to Garth's Dispensary; the subject of which was the disputes then subsisting between the fellows and licentiates.

The life of Thornton was not destined to attain any great extension: in the prime of his days, while he was surrounded by domestic felicity, the comforts of fortune,

tune, and the reſpect of ſociety, ill health came upon him; and medical aid proving inefficient, he died, of the gout in his ſtomach, May 9. 1768, at only 44 years of age. His wife, a daughter, and two ſons, ſurvived him. Beſides the productions already mentioned, he wrote the papers in the Adventurer marked A; "An Ode to St Cecilia's day, adapted to the ancient British Muſic," a burleſque performance; "The Oxford Barber;" with many detached eſſays in the public papers. A few letters addreſſed to his Sylvia before they were married, diſplay great tenderneſs, expreſſed with frankneſs and eaſe. A ſmall edition of his works might, with much propriety, be preſented to the public, before it ſhall be too late to aſcertain them all. His character may be taken from his epitaph, written in Latin by his friend Dr Warton, and placed on his monument in Weſtminſter Abbey. It is to this effect: "His genius, cultivated moſt happily by every kind of polite literature, was accompanied and recommended by manners open, ſincere, and candid. In his writings and converſation he had a wonderful livelineſs, with a vein of pleaſantry peculiarly his own. In ridiculing the failings of men, without bitterneſs, and with much humour, he was ſingularly happy; as a companion, he was delightful."

THUNDER. There is not one of the appearances of nature which has ſo much engaged the attention of mankind as thunder. The ſavage, the citizen, and the philoſopher, have obſerved it with dread, with anxiety, and with curioſity; and the philoſopher of our times treats the others with a ſmile of condeſcenſion, while he here enjoys the fulleſt triumph of his ſuperiority.

> *Felix qui potuit rerum cognoſcere cauſas,*
> *Atque metus omnes et inevitabile fulmen*
> *Subjecit pedibus.*

But though this grand phenomenon has long engaged the curious attention of philoſophers, it is but very lately that they have been able to explain it; that is, to point out the more general law of nature of which it is a particular inſtance. Inflammable vapours had long furniſhed them with a ſort of explanation. The diſcovery of gunpowder, and ſtill more that of inflammable air, gave ſome probability to the exiſtence of extenſive ſtrata of inflammable vapours in the upper regions of the atmoſphere, which, being ſet on fire at one end, might burn away in rapid ſucceſſion, like a train of gunpowder. But the ſmalleſt inveſtigation would ſhew ſuch a diſſimilarity in the phenomena, and in the general effects, that this explanation can have no value in the eyes of a true naturaliſt. Horrid exploſion, and a blaſt which would ſweep every thing from the ſurface of the earth, muſt be the effects of ſuch inflammation. The very limited and capricious nature of the ravages made by thunder, render them altogether unlike exploſions of elaſtic fluids.

No ſooner were the wonderful effects of the charged electrical phial obſerved, than naturaliſts began to think of this as exhibiting ſome reſemblance to a thunderſtroke (ſee ELECTRICITY, *Encycl.* nº 12); but it was not till toward the year 1750 that this reſemblance was viewed in a proper light by the celebrated Franklin. In a diſſertation written that year, he delivers his opinion at large, and notices particularly the following circumſtances of ſimilarity.

Thunder, in ſeveral remarkable particulars.

1. The colour and crooked form of lightning, perfectly ſimilar to that of a vivid electrical ſpark between diſtant bodies, and unlike every other appearance of light. This angular, deſultory, capricious form of an electrical ſpark, and of forked lightning, is very ſingular. No two ſucceſſive ſparks have the ſame form. Their ſharp angles are unlike every appearance of motion through unreſiſting air. Such motions are always curvilineal. The ſpark is like the ſimultaneous exiſtence of the light in all its parts; and the fact is, that no perſon can poſitively ſay in which direction it moves.

2. Lightning, like electricity, always ſtrikes the moſt advanced objects—hills, trees, ſteeples.

3. Lightning affects to take the beſt conductors of electricity. Bell wires are very frequently deſtroyed by it. At Leven houſe in Fifeſhire, in 1733, it ran along a gilded moulding from one end of the houſe to the other, exploding it all the way, as alſo the tinfoil on the backs of ſeveral mirrors, and the gilding of ſcreens and leather hangings.

4. It burns, explodes, and deſtroys theſe conductors preciſely as electricity does. It diſſolves metals; melts wires; it explodes and tears to pieces bodies which contain moiſture. When a perſon is killed by lightning, his ſhoes are commonly burſt. When it falls on a wet ſurface, it ſpreads along it. The Royal William, in Louiſburgh harbour, in 1758, received a thunderſtroke, which diſſipated the maintop-gallant maſt in duſt, and came down on the wet decks in one ſpark, which ſpread over the whole deck as a ſpout of water would have done. This is quite according to electrical laws.

5. It has ſometimes ſtruck a perſon blind. Electricity has done the ſame to a chicken which it did not kill.

6. It affects the nervous ſyſtem in a way reſembling ſome of the known effects of electricity. The following is a moſt remarkable inſtance: —— Campbell, Eſq; of Succoth, in Dunbartonſhire, had been blind for ſeveral years. The diſorder was a gutta ſerena. He was led one evening along the ſtreets of Glaſgow by his ſervant Alexander Dick, during a terrible thunder ſtorm. The lightning ſometimes fluttered along the ſtreets for a quarter of a minute without ceaſing. While this fluttering laſted, Mr Campbell ſaw the ſtreet diſtinctly, and the changes which had been made in that part by taking down one of the city gates. When the ſtorm was over, his entire blindneſs returned.—We have from a friend another inſtance, no leſs remarkable. One evening in autumn he was ſitting with a gentleman who had the ſame diſorder, and he obſerved ſeveral lambent flaſhes of lightning. Their faces were turned to the parlour window; and immediately after a flaſh, the gentleman ſaid to his wife "Go, my dear, make them ſhut the white gate; it is open, you ſee." The lady did ſo, and returned; and, after a little, ſaid, "But how did you know that the gate was open?" He exclaimed, "My God! I ſaw it open, and two men look in, and go away again," (which our friend alſo had obſerved). The gentleman, on being cloſe queſtioned, could not recollect having had another glance, nor why it had not ſurpriſed him; but of the glimpſe itſelf he was certain, and deſcribed the appearance very exactly.

7. Lightning kills; and the appearances perfectly reſemble

reſemble thoſe of a mortal ſtroke of electricity. The muſcles are all in a ſtate of perfect relaxation, even in thoſe ſituations where it is uſually otherwiſe

8 Lightning is well known to deſtroy and to change the polarity of the mariner's needle.

Dr Franklin was not contented with the bare obſervation of theſe important reſemblances. He availed himſelf of many curious diſcoveries which he had made of electrical laws. In particular, having obſerved that electricity was drawn off at a great diſtance, and without the leaſt violence of action, by a ſharp metallic point, he propoſed to philoſophers to erect a tall maſt or pole on the higheſt part of a building, and to furniſh the top of it with a fine metalline point, properly inſulated, with a wire leading to an inſulated apparatus for exhibiting the common electrical appearances. To the whole of this contrivance he gave the name of *thunder-rod*, which it ſtill retains. He had not a proper opportunity of doing this himſelf at the time of writing his diſſertation in a letter from Philadelphia to the Royal Society of London; but the contents were ſo ſcientific, and ſo intereſting, that in a few weeks time they were known over all Europe. His directions were followed in many places. In particular, the French academicians, encouraged by the preſence of their monarch, and the great ſatiſfaction which he expreſſed at the repetition of Dr Franklin's moſt inſtructive experiments, which diſcovered and eſtabliſhed the theory of poſitive and negative electricity, as it is ſtill received, were eager to execute his orders, making his grand experiment, which promiſed ſo fairly to bring this tremendous operation of nature not only within the pale of ſcience, but within the management of human power.

But, in the mean time, Dr Franklin, impatient of delay, and perhaps incited by the honourable deſire of well-deſerved fame, put his own ſcheme in practice. His inventive mind ſuggeſted to him a moſt ingenious method of preſenting a point to a thunder cloud at a very great diſtance from the ground. This was by fixing his point on the head of a paper kite, which the wind ſhould raiſe to the clouds, while the wet ſtring that held it ſhould ſerve for a conductor of the electricity. We preſume that it was with a palpitating heart that Dr Franklin, unknown to the neighbours, and accompanied only by his ſon, went into the fields, and ſent up his meſſenger that was to bring him ſuch news from the heavens. He told a perſon, who repeated it in the hearing of the preſent writer, that when he ſaw the fibres of the cord raiſe themſelves up like hogs briſtles, he uttered a deep ſigh, and would have wiſhed that moment of joy to have been his laſt. He obtained but a few faint ſparks from his apparatus that day; but returned to his houſe in a ſtate of perfect happineſs, now feeling that his name was never to die. Thus did the ſoap-bubble, and the paper kite, from being the playthings of children, become, in the hands of Newton, and of Franklin, the means of acquiring immortal honour, and of doing the moſt important ſervice to ſociety.

We may juſtly conſider this as one of the greateſt of philoſophical diſcoveries, and as doing the higheſt honour to the inventor; for it was not a ſuggeſtion from an accidental obſervation, but aroſe from a ſcientific compariſon of facts, and a ſagacious application of the doctrine of poſitive and negative electricity; a doctrine wholly Dr Franklin's and the reſult of the moſt acute and diſcriminating obſervation. It was this alone that ſuggeſted the whole; and by explaining to his ſatisfaction the curious property of ſharp points, gave him the courage to handle the thunderbolt of Jove.

Thunder.

It is then a point fully aſcertained, that thunder and lightning are the electric ſnap and ſpark, as much ſuperior to our puny imitations as we can conceive from the immenſe extent of the inſtruments in the hands of Nature. If, ſays Dr Franklin, a conductor one foot thick and five feet long will produce ſuch ſnaps as agitate the whole human frame, what may we not expect from a ſurface of 10,000 acres of electrified clouds? How loud muſt be the exploſion? how terrible the effects?

Electrical ſtate of the air.

This diſcovery immediately directed the attention of philoſophers to the ſtate of the atmoſphere with reſpect to electricity; and in this alſo Dr Franklin led the way. He immediately erected his thunder rods; and they have been imitated all over the world, with many alterations or improvements, according to the different views and ſkill of their authors. It is needleſs to inſiſt here on their conſtruction. They have been deſcribed in the article ELECTRICITY (*Ency. l.*); and any perſon well acquainted with its theory, as laid down in the *Supplementary* article ELECTRICITY, will be at no loſs to accommodate his own conſtruction to his ſituation and purpoſes.

Dr Franklin took the lead, as we have already obſerved, in this examination of the electrical ſtate of the atmoſphere. He ſeldom found it without giving ſigns of electricity, and this was generally negative. See *Phil. Tranſ.* Vol. XLVIII. p. 358. and 785.

Mr Canton repeated thoſe experiments, and found the ſame reſults; both, however, found that the electricity would frequently change from poſitive to negative, and from negative to poſitive, in very ſhort ſpaces of time, as different portions of clouds or air paſſed the thunder-rod.

5 Cautions to be obſerved in the examination by a thunder rod.

We muſt here remark, that our acquaintance with the laws of electricity ſufficiently informs us, that the electricity of our thunder rod may frequently be of a different kind from that of the cloud which excites the appearances at our apparatus. We know that air, like glaſs, is a non-conductor; and that when it is brought into any ſtate of electricity, either by communication, or by mere induction, it will remain in that ſtate for ſome time, and that it always changes its electricity *per ſtratum*. A poſitive cloud, in the higher regions of the atmoſphere, will render the air immediately below it negative, and a ſtratum below that poſitive. If the thunder rod be in this poſitive ſtratum, it will exhibit poſitive electricity; but if the cloud be conſiderably nearer, the rod, by being in the adjoining negative ſtratum, may ſhow a negative electricity, which will exceed the poſitive electricity which the diſtant poſitive cloud would have induced on its lower end by mere poſition, had the intervening air been away. This exceſs of negative electricity muſt depend on the degree in which the ſurrounding ſtratum of air has been rendered negative. If this has been the almoſt inſtantaneous effect of the preſence of the poſitive cloud, it cannot be rendered ſo negative as to produce negative electricity in the lower

end

2

water, by the iron and coaly matters, which are expoſed to the joint action of fire and water. Theſe two electricities will be oppoſite; or when not oppoſite, will not be equal: in either of which caſes, we have vaſt maſſes of ſteam in ſtates fit for flaſhing into each other.

A fact more to our purpoſe is, that if a ſilk or linen cloth, of a downy texture, be moiſtened or damped, and hung before a clear fire to dry, the fibres briſtle up, and on bringing the finger, or a metal knob, near them, they are plainly attracted by it. We found them negatively electric. This ſhews that the ſimple ſolution of water in air produces electricity. And this is the chief operation in Nature connected with the ſtate of the atmoſphere. It is thus that the watery vapours from all bodies, and particularly the copious exſudation of plants, diſappear in our atmoſphere. There can be no doubt but that the oppoſite electricity will be produced by the precipitation of this vapour; that is, by the formation of clouds in clear air. When damp, but clear air in one veſſel expands into an adjoining veſſel, from which the air has been exhauſted, a cloud appears in both, and a delicate electrometer is affected in both veſſels; but our apparatus was not fitted for aſcertaining the kind of electricity produced. Here then is another unexplored field of experiment. We got two veſſels made, having diaphragms of thin ſilk. Theſe were damped, and ſet into two tubs of water, of very different temperatures. Dry air was then blown thro' them, and came from their ſpouts ſaturated with water. The ſpouts were turned toward each other. Being of very different temperatures, the ſtreams produced a cloud upon mixing together, and a ſtrong negative electricity was produced. We even found that an electrometer, placed in a veſſel filled with condenſed air, was affected when this air was allowed to ruſh out by a large hole.

Laſtly, we know that the tourmaline, and many of the columnar cryſtals, are rendered electrical by merely heating and cooling. Nay, Mr Canton found that dry air became negative by heating, and poſitive by cooling, even when it was not permitted to expand or contract.

When water is precipitated, and forms a cloud, it is reaſonable to expect that it will have the electricity of the air from which it is precipitated. This may be various, but in general negative: For the heat by which the air was enabled to diſſolve the water made it negative; and much more the friction on the ſurface of the earth. But as heat cauſed it to diſſolve the water, cold will make it precipitate it; and we ſhould therefore expect that the air will be in the ſtate in which it was when it took up the water. But if it be cooled ſo faſt as to precipitate it in the form of rain, or ſnow, or hail we may expect poſitive electricity. Accordingly, in ſummer, hail ſhowers always ſhew ſtrong poſitive electricity; ſo does ſnow when falling dry.

Here, then, are copious ſources of atmoſpheric electricity. The mere expanſion and condenſation of the air, and ſtill more the ſolution and precipitation of watery vapours in it, are perhaps ſufficient to account for all the inequality of electric ſtate that we obſerve in the atmoſphere.

The maſſes of air thus differently conſtituted are evidently diſpoſed in ſtrata The clouds are ſeen to be ſo. Theſe clouds are not the ſtrata, but the boundaries of ſtrata; which, from the very nature of things, are in different ſtates with reſpect to the ſuſception or precipitation of water. When two ſuch ſtrata are thus adjoining, they will ſlowly act on each other's temperature, and by mixing will form a thin ſtratum of cloud along their mutual confines. If the one ſtratum has any motion relative to the other, and be in the ſmalleſt degree diſturbed, they will mix to a greater depth in each; and this mixture will not be perfectly uniform. The extreme mobility of air will greatly increaſe this jumble of the adjoining parts of the two ſtrata, and will give the cloud a greater thickneſs. If the jumble has been very great, ſo as to puſh one of them through the other, we ſhall have great towering clouds, perhaps pervading the whole thickneſs of the ſtratum of air. We take theſe clouds to be like great foggy bladders, ſuperficially opaque where they have come into contact with the ſurrounding ſtratum of air, but tranſparent within.

9 Strata of the atmoſphere are of different ſtates of electricity, and are tranſparent.

When the wind, or ſtratum in motion, does not puſh all the quieſcent air before it, it generally gets over it, and then flows along its upper ſide, and, by a partial mixing, produces a fleecy cloud, as already deſcribed. We may obſerve here, by the way, that the motion of thoſe fleecy clouds is by no means a juſt indication of the motion of the ſtratum; it is nearly the motion compoſed of the half of the motions of the two.

10 Theſe ſtrata have ſtrata of clouds interpoſed.

This is in all probability the ſtate of the atmoſphere, conſiſting of ſtrata of clear air many hundred yards thick, ſeparated from each other by thin fleeces of clouds, which have been produced by the mixture of the two adjoining ſtrata. This is no fancy; for we actually ſee the ſky ſeparated by ſtrata of clouds at a great diſtance from each other. And we ſee that theſe ſtrata maintain their ſituations, without farther admixture, for a long time, the bounding clouds continuing all the while to move in different directions. In the year 1759, during the ſiege of Quebec, a hard gale blew one day from the weſtward, which made it almoſt impracticable to ſend a number of proviſion boats to our troops ſtationed above the town. While the men were tugging hard at the oars againſt the wind, and hardly advancing, though the tide of flood favoured them, the French threw ſome bombs to deſtroy the boats. One of theſe burſt in the air, near the top of its flight, which was about a quarter of a mile high. The round ball of ſmoke produced by the exploſion remained in the ſame ſpot for above ſeven minutes, and diſappeared by gradual diffuſion. The lower air was moving to the eaſtward at leaſt 30 feet per ſecond.

In 1783, when a great fleet rendezvouſed in Leith Roads, the ſhips were detained by an eaſterly wind, which had blown for ſix weeks without intermiſſion. The ſky was generally clear; ſometimes there was a thin fleece of clouds at a great height, moving much more ſlowly in the ſame direction with the wind below. During the laſt eight days, the upper current was from the weſtward, as appeared by the motion of the upper clouds. High towering clouds came down the river, with a little rain; the ſtrata were jumbled, and the whole atmoſphere grew hazy and uniform; then came thunder, and heavy rain, and the wind below ſhifted to the weſtward.

Thus it is ſufficiently evinced, that the atmoſphere frequently conſiſts of ſuch ſtrata, well diſtinguiſhed from each

Thunder.

each other: their appearance and progreſs leave us no room to doubt but that they come from different quarters, and had been taken up or formed at different places, and in different circumſtances, and therefore differing in reſpect of their electrical ſtates.

11 The electric equilibrium is reſtored very ſlowly in general.

The conſequence of their continuing long together would be a gradual but ſlow progreſs of their electricity to a ſtate of equilibrium. The air is perhaps never in a perfectly dry ſtate, and its moiſture will cauſe the electricity to diffuſe itſelf gradually. It is not beyond the power of our mathematics to aſcertain the progreſs of this approximation to the electric equilibrium. We ſee ſomething very like it in the curious experiments of Beccaria with mirror plates laid together, and charged by means of a coating on the outer plates. Theſe plates were found to conſiſt of alternate ſtrata of poſitive and negative electricity, which gradually penetrated through the plates, and coaleſced till they were reduced to two ſtrata; perhaps in time the electricity would have diſappeared entirely by theſe two alſo coaleſcing. In the ſame manner there would be a ſlow transfuſion of ſenſible electricity through theſe ſtrata without any ſenſible appearances. If any collateral cauſes ſhould make a part more damp than the reſt, there would be a more briſk transference through it, accompanied with faint flaſhes of lambent lightning.

12 A rapid and extenſive reſtoration is a thunder clap.

But thunder requires a rapid communication, and a reſtoration of electric equilibrium in an inſtant, and to a vaſt extent. The means for this are at hand, furniſhed by Nature. The ſtrata of charged air are furniſhed with a coating of cloud. The lower ſtratum is coated on the underſide by the earth.

13 Manner in which this is effected by a coating of cloud.

When a jumble is made in any of the ſtrata, a precipitation of vapour muſt generally follow. Thus a conductor is brought between the electrical coatings. This will quickly enlarge, as we ſee that in our little imitations the knobs of our conductors inſtantaneouſly arrange any particles of duſt which chance to lie in the way, in ſuch a manner as to complete the line of conduct, and occaſion a ſpark to fly to a much greater diſtance than it would have leaped if no duſt had been interpoſed. We have often procured a diſcharge between two knobs which were too far aſunder, by merely breathing the damp air between them. In this manner the interpoſed cloud immediately attracts other clouds, grows ragged by the paſſage of electricity through clear air, where it cauſes a precipitation by altering the natural equilibrium of its electricity; for a certain quantity of electricity may be neceſſary for air's holding a certain quantity of vapour. Accordingly we ſee in a thunder ſtorm that ſmall clouds continually and ſuddenly form in parts formerly clear. Whatever cauſes thunder, does in fact promote this precipitation.

Theſe clouds have the electricity of the ſurrounding air, and muſt communicate it to others in an oppoſite ſtate, and within reach. They muſt approach them, and muſt afterwards recede from them, or from any that are in the ſame ſtate of electricity with themſelves. Hence their ragged forms, and the ſimilar form of the under ſurface of the great cloud; hence their continual and capricious ſhifting from place to place: they are carriers, which give and take between the other clouds, and they may become ſtepping ſtones for the general diſcharge.

If a ſmall cloud form a communication with the ground, and the great cloud be poſitive or negative, we muſt have a complete diſcharge, and all the electrical phenomena, with great violence; for this coating of vapour is abundantly complete for the purpoſe. It conſiſts of ſmall veſicles, which are ſufficiently near each other for diſcharging the whole air that is in their interſtices A phial coated with amalgam is by no means fully coated. If we hold it between the eye and the light, we ſhall ſee that it is only covered with a number of detached points of amalgam, which looks like a cobweb. Yet this glaſs is almoſt completely diſcharged by a ſingle ſpark, the reſiduum being hardly perceptible.

14 The discharge is commonly between the clouds.

The general ſcene of thunder is the heavens; and it is by no means a frequent caſe that a diſcharge is made into the earth. The air intervening between the earth and the loweſt coating is commonly very much confuſed in conſequence of the hills and dales, which, by altering the currents of the winds, toſs up the interior parts, and mix them with thoſe above. This generally keeps the earth pretty much in the ſame electrical ſtate as the loweſt ſtratum of clouds.

15 Which are horizontally diſtant.

Nor are the great thunder ſtorms in general inſtances of the reſtoration of equilibrium between two ſtrata immediately incumbent on each other. They ſeem, for the moſt part, to be ſtrokes between two parcels of air which are horizontally diſtant. This, however, we do not affirm with great confidence. Our chief reaſon for thinking ſo is, that in theſe great ſtorms the ſpark or ſhaft of forked lightning is directed horizontally, and ſometimes is ſeen at once through an extent of ſeveral miles.

16 Particular account of forked lightning, and explanation of the long continued and rumbling noiſe of thunder.

The nature of this ſpark has not, we think, been properly conſidered. It is ſimply compared to a long electrical ſpark, which we conceive to be drawn thro' pure air, and is conſidered as marking the actual transference of electricity from one end to the other. But this we doubt very much. We are certain of having obſerved ſhafts of lightning at one and the ſame inſtant ſtretching horizontally, though with many capricious zigzags and lateral ſputterings, at leaſt five miles. We cannot conceive this to have been the ſtriking diſtance, becauſe the greateſt vertical diſtance of the ſtrata is not the half of this. We rather think that it is a ſimultaneous range of diſcharges, each accompanied with light, differently bright, according to the electrical capacity of the cloud into which it is made; and if there is a real tranſference of electric matter on this occaſion (which we do not affirm), it is only of a ſmall quantity from one cloud to the next adjoining. This we think confirmed by the ſound of thunder. It is not a ſnap, incomparably louder than our loudeſt ſnap from coated glaſs; but a long continued, rumbling, and *very unequable* noiſe. There is no doubt but that this ſnap was almoſt ſimultaneous through the whole extent of the ſpark; but its different parts are conveyed to our ear in time, and are therefore heard by us in ſucceſſion; and it is not an uniform roar, but a rumbling noiſe, unequally loud, according as the different parts of the ſnap are indeed differently loud. We ſhould hear a noiſe of the ſame kind if we ſtood at one end of a long line of ſoldiers, who diſcharged their muſquets (differently loaded) in the ſame inſtant. When any part of the ſpark is very near us, and is not very diffuſe, the ſnap begins with great ſmartneſs, and continues for ſome time, not unlike the violent tearing of a piece of ſtrong ſilk; after which it becomes more and more mellow

Thunder. low as it comes from a greater distance. We do not, however, affirm, that the whole extensive spark and snap are co-existent or simultaneous. The cloud is, in all probability, but an indifferent conductor, and even a sensible time may elapse during the propagation of the spark to a great distance. Beccaria observed this in a line of 250 feet of chain, lying loosely on the ground, and consisting of near 6000 links. He thought that it employed a full second; but when the chain was gently stretched, the communication seemed instantaneous.

17 Observations of the electric spark.

We cannot help thinking that even the electrical snap between two metal knobs is of the same kind. Not a quantity of luminous matter which issues from the one and goes to the other, but a light that is excited or produced in different material interjacent particles of air or other interposed matter. The angular and sputtering quite incompatible with the motion of a simple luminous point. Nay, our chemical knowledge here comes in aid, and obliges us to speculate about the manner in which this light is produced. Whence does it come? It may be produced by two knobs of ice. We know that water consists of vital and inflammable air, which have already emitted the light which made an ingredient of their composition. The spark therefore does not come from the ice. Is it then from the air? If so, perhaps water is produced, or rather something else, for there is not always inflammable air at hand to compose water. Yet the transference of electricity has decomposed the air, or has robbed it of part of its light. The remainder may not be water; but it is no longer air. Is not this confirmed by the peculiar smell which always accompanies electric sparks? and the peculiar taste, not unlike the taste felt on the tongue when it is touched by the zinc in the experiments on Galvanism? Even the fine pencil of light which flows from a point positively electrified, appears through a magnifying glass to consist, not of luminous lines, but of lines of luminous points. And these points are of different brilliancy and different colour, both of which are incessantly changing. And be it farther observed, that these lines are curves, diverging from each other, and convex to the axis. This circumstance indicates a mutual repulsion, arising, in all probability, from the expansion of the air. And, lastly, no spark nor light of any kind can be obtained in a space perfectly void of air.

All these circumstances concur in explaining the nature of the shaft of forked lightning. It is a series of appearances excited in the intervening medium, and which produce some chemical change in it. Thunder, when it strikes a house, always leaves a peculiar smell. Inflammable air has also a peculiar and very disagreeable smell. The smell produced by electricity greatly resembles the smell produced by striking two pieces of quartz together.

18 Deluc's notion of thunder not probable.

Mr Deluc supposes that the electrical spark, as it is exhibited in thunder, is always accompanied by the decomposition of air now so familiarly known, and that this is the origin of the deluge of rain which commonly finishes the storm. But this is not in the smallest degree probable. The decomposition extends surely no farther than where the light is separated; and we should no more expect a deluge of rain, even if we had inflammable air ready at hand, than we expect drops of water in our electrical experiments. Something different from water follows this decomposition, total or partial, of the vital air; and the water which we do observe to accompany thunder, is no more than what we should expect from the copious precipitation of water in a cloudy form. Mr Saussure's observations assure us, that the particles of a cloud are vesicles. Indeed no person who has looked narrowly at a fog, or has observed how large the particles are of the cloud which forms in a receiver when we suddenly diminish the density of the air, and who observes how slowly these particles descend, can doubt of their being hollow vesicles. We cannot perhaps explain their formation; but there they are. We can hardly conceive them receiving the commotion which accompanied the snap without collapsing by the agitation. Perhaps the very cessation of their electricity may produce this effect. They will therefore no longer float in the air, but fall, and unite, and come to the ground in rain. We may expect this rain to be copious, for it is the produce of two strata of clouds. It greatly contributes to the putting an end to the storm, by passing through the strata, and helping to restore the equilibrium.

19 Why and how thunder may continue for some time.

One may at first expect that a single clap of thunder will restore the equilibrium of any extent of clouds, and we require an explanation of their frequent repetition before this is accomplished. This is not difficult, and the fact is a confirmation of the above theory, which is considerably different from the generally received notions of the subject. We consider the stratum of clear air as the charged electric; positive on one side, and negative on the other, and coated with conducting clouds. When the discharge is made, the state of electricity is indeed changed through the whole stratum, but the equilibrium is by no means completed. The stratum is perhaps a quarter of a mile in thickness. The discharge does not immediately affect all this; but does it superficially, leaving the rest unbalanced. It is like the residuum which is left in a Leyden phial when the discharge has been made by means of a spark drawn at a distance. It is still more like the residuum of the discharge of a Leyden phial that is coated only in patches on one side. Each of these patches discharge what is immediately under it and round it to a certain small distance, but leaves a part beyond this still charged. This redundant electricity gradually diffuses itself into the spaces just now discharged; and, after some considerable time has elapsed, another discharge may be made. In like manner, the electricity remaining in the interior of the stratum diffuses itself, comes within the action of the coating, and may be again discharged by a clap of thunder. We have a still better parallel to this in Beccaria's experiments with two or more plates of glass laid together. After the first discharge, the internal surfaces will exhibit certain electricity. Lay the plates together, and, after some time, the electricity of the inner surfaces will be different, and another discharge may be obtained.

Magnetism affords the best illustration of this. If a magnet be brought near a piece of soft iron, lying below a paper on which iron filings are lightly strewed, it will instantly induce a north pole on one end and a south pole on the other; and this will be distinctly observed by the way in which these filings will arrange themselves. But if, instead of soft iron, we place a bar of hard tempered steel, the south pole will be but a small

Thunder

small matter removed from the north pole; but by continuing the magnet long in the same place, the distribution of magnetism in the piece of hard steel will gradually advance along the bar, and after a long time the neutral point will be almost in the middle of the bar, and the south pole will be at the farther end. See MAGNETISM in this *Suppl*

20
Most thunder strokes are RETURNING STROKES

We said that the clouds were the usual scenes of the violent electric phenomena. We imagine that the greatest part of the thunder strokes which have been felt have been of the kind which Lord Mahon, now Lord Stanhope, calls the returning stroke. If two clouds A and B are incumbent over the plain *a* and *b*; and if A be positive and B negative the earth will be maintained in a negative state at *a*, and a positive state at *b*. If the discharge be now made between the clouds A and B, the electricity must instantly rush up through a conductor at *a*, and down through one at *b*, and each place will have a stroke. The same thing will happen if the negative cloud B is above the positive cloud A, but not in so great a degree; for the negative electricity at *a* will now be much less than in the other case, because it is induced only by the prevalence of the positive cloud A over the more remote negative cloud B.

— B

+ b

This returning stroke explains, much better than we can by any direct stroke, the capricious effects of thunder A person at Vienna received a terrible shock by having his hand on a thunder-rod during a violent explosion which he saw above three miles distant. Sparks are observed at thunder rods at every the most distant flash of lightning.

21
Beccaria's theory of thunder not just.

Beccaria has a different theory of thunder. He imagines that the different parts of the earth are in different states of electricity, and that the clouds are the restoring conductors. But this does not accord with what we know of electricity. The earth is so good a conductor, that Dr Watson could not observe any time lost in communicating the electricity to the distance of more than four miles. It is very true, that the earth is almost always in a state of very unequal, and even opposite, electricity in its different parts; but this arises from the variety of clouds strongly electrified in the opposite way This induces electricity, or disturbs the natural uniform diffusion of electricity, just as the bringing magnets or loadstones into the neighbourhood of a piece of iron, without touching it, renders it magnetical in its different parts. While they continue in their places, the piece of iron will be magnetical, and differently so in its different parts.

Such are the thoughts which occur to us on this subject. But we by no means affirm that we have given a full account of the procedure of Nature; we have only pointed out several necessary consequences of the known laws of electricity, and of its production in the atmosphere by means of natural operations which are continually going on. These *must* operate, and produce an electrical state of the atmosphere greatly resembling what we observe: and we have shewn, from the acknowledged doctrines of electricity, how this want of equilibrium may be removed, and must be removed, by the same operations of Nature. The equilibrium must be restored by means of the conducting coating furnished by the clouds. But these may be the least considerable of Nature's resources; and the subject is still an unexplored field, in the examination of which we may hope to make great progress, in consequence of our daily increasing knowledge of the chemical state of the atmosphere.

22
Dr Franklin's invention of a guard against thunder.

Knowledge is valuable chiefly as it is useful. No man ever saw the propriety of this apothegm more strongly than Dr Franklin, or more assiduously adhered to it in the course of a long and studious life. However greatly we may admire his sagacity, penetration, and logical discrimination, in the discoveries he has made in the science of electricity, and his discovery of the identity of electricity and thunder, we must acknowledge infinitely greater obligations to him for putting it in our power to ward off the fatal, and formerly inevitable stroke, of this awful agent in the hands of Nature.

Dr Franklin considers the earth as performing the office of conductor in restoring the electric equilibrium of the atmosphere, which has been disturbed by the incessant action of the unwearied powers of Nature.

He observes that the usual preference will be given to the best conductors. In this respect, a metal rod far surpasses the brick, stone, timber, and other materials which compose our buildings, especially when they are dry, as is usually the case in the thundery season. He therefore advises us to place metalline conductors in the way of the atmospherical electricity, in those places where it is most likely to strike, and to continue them down to the moist earth, at some depth under the surface. Nay, as it has been found that thunder has not in every instance struck the highest parts of buildings, he advises to raise the metalline conductors to some considerable height above the building, the more certainly to invite the electricity to take this course.

23
Directions for constructing it.

To ensure success, he observes that the electrical shock dissipates water, and even metalline conductors, when too small. He therefore advises to make the conductor at least half an inch square, none of that size having ever been destroyed, though smaller have, by the thunder; yet even these had conducted the thunder to the ground with perfect safety to the building.

No part of a conductor must terminate in the building; for the electricity accumulates exceedingly at the remote extremities of all long rods, and tends to fly off with great force, especially if another conductor is near. This aids the accumulation, by acquiring at its upper end an electricity opposite to that of the lower end of the other: and this effect, produced by the influence of a positive cloud, makes the upper and negative end of the lower portion of a divided conductor draw more electricity to the lower end of the upper portion. This redundant electricity, strongly attracted by the negative lower portion, flies off with great violence through the air; or if surrounded with any matter capable of conversion into elastic vapour by heat, bursts it with irresistible force. Thus the thunder, acting on the vane spindle of St Bride's steeple in London, sprung from its lower end to the upper end of an iron window bar, and burst the stone in which it was fixed, by expanding the moisture into steam. In like manner it burst the stone at the lower end of this bar, to make its way to an iron cramp which connected the opposite sides of the steeple; from this it struck to another cramp; and so from

cramp to cramp, till it reached the gutter leads of the church, burſting and throwing off the ſtonework in many places.

All interruptions muſt therefore be carefully avoided, and the whole muſt be made as much as poſſible one continued metal rod.

Farther, Dr Franklin, obſerving the ſingular property which ſharp points poſſeſs of drawing off the electricity in ſilence, adviſes us to finiſh our conductor with a fine point of gilt copper, which cannot be blunted by ruſt.

24
Is the common conductor an effectual and ſafe contrivance?

But as thus raiſing the conductor, and pointing it, are ſo many invitations to the thunder to take this courſe; and as we cannot be certain that the quantity thus invited may not be more than what the rod can conduct with ſafety—it has appeared to Dr Wilſon, and other able electricians, that it will be ſafer to give abundance of conduct to what may unavoidably viſit us, without inviting what might otherwiſe have gone harmleſsly by.

This was attentively conſidered by Dr Franklin, Dr Watſon, Mr Canton, Dr Wilſon, and others, met as a committee of the Royal Society, at the deſire of the Board of Ordnance, to contrive a conductor for the powder magazine at Purfleet.

We think that the theory of induced electricity, founded on Dr Franklin's diſcoveries, and confirmed by all the later inventions of the electrophorus, condenſer, &c. will decide this queſtion in the moſt ſatisfactory manner.

25
Scientific account of the ſtate of electricity induced on a building by a thunder cloud,

When a cloud poſitively electrified comes over a building, it renders it negatively electrical in all its parts, if of conducting materials, and even the ground on which it ſtands. This effect is more remarkably produced if the ſtructure is of a tall and ſlender ſhape, like a ſteeple or a rod. Therefore the external electrical fluid is attracted by the building with greater force than if it had conſiſted of materials leſs conductive. A diſcharge will therefore be made through it in preference to any neighbouring building, becauſe it is more eminently negative. For the ſame reaſon, if there are two buildings equal and ſimilar, one of them being a good conductor, and the other being a leſs perfect one, the perfect conductor, becoming more powerfully negative, the cloud will become more ſtrongly poſitive over this houſe than over the other, and the ſtroke will be made through it.

26
And on the thunder rod.

The ſame thing muſt obtain in a perfect conductor continued from the top to the foundation of a houſe, built of worſe conducting materials. The conductor becoming more eminently negative than any other part of the building, the electric fluid will be more ſtrongly attracted by it, accumulated in its neighbourhood, and will all be diſcharged through it, ſo long as it is able to conduct.

If the building is of great extent, the proximity of one part of the building to the thunder cloud may produce an accumulation of electrical fluid in its neighbourhood, in preference to a more perfect, but remote, conductor. But when the diſtances from the cloud are not very unequal, the accumulation will always be in the neighbourhood of the perfect conductor; and this will determine the diſcharge that way. The accumulation in the neighbourhood of the rod will be ſmall indeed, when the rod is ſmall; but then it is denſe, and the whole of electric phenomena ſhew that it is the denſity, and not the quantity, of accumulation which produces the violent tendency to fly off: it is this alone which makes it impoſſible to confine electricity in a body which terminates in a ſharp point.

For the ſame reaſon, bodies of the ſame materials and ſhape will increaſe the accumulation in the adjoining part of the cloud in proportion as they are nearer to it, or more advanced beyond the reſt of the building.

And bodies of ſlender ſhape, and pointed, will produce this accumulation in their neighbourhood in a ſtill more remarkable degree, and determine the courſe of the diſcharge with ſtill greater certainty.

But it is evident that a metallic rod, no higher than the reſt of the building, may occaſion an accumulation in the adjoining part of a near thunder cloud ſufficient to produce a diſcharge, when the building itſelf, conſiſting of imperfect conductors, would not have provoked the diſcharge at all. It may therefore be doubted whether we have derived any advantage from the conductor.

27
Effect of all interruptions in the conductor.

To judge properly of this, we muſt conſider houſes as they really are, conſiſting of different materials, in very different ſhapes and ſituations; and particularly as having many large pieces of metal in their conſtruction, in various poſitions with regard to the cloud, the ground, and to each other. Suppoſe all the reſt of the building to be of non-conducting materials. When a poſitive thunder cloud comes overhead, every piece of metal in the building becomes electrical, without having received any thing as yet from the cloud; that end of each which is neareſt the cloud becoming negative, and the remote end poſitive. But, moreover, the electricity of one increaſes the electricity of its neighbour. Then the moſt elevated becomes more ſtrongly attractive at its upper end than it would have been had the others been away; and therefore produces a greater accumulation in the nearer part of the thunder cloud than it would otherwiſe have done, and it will receive a ſpark. By this its lower end becomes more overcharged, and this makes the upper end of the next more undercharged, and the ſpark is communicated to it, and ſo on to the ground; which would not have happened without this ſucceſſion of conductors. Thus it is eaſy to conceive, that the accumulation in the cloud is juſt inſufficient to produce a diſcharge—While things are in this ſtate, juſt ready to ſnap, ſhould a man chance to paſs under a bell wire, or under a luſtre hanging by a chain, his body will immediately augment the poſitive electricity of the lower end of the conductor above him, and thus will augment the negative electricity of its upper end. This again will produce the ſame effect in the conductor above it: and thus each conductor becomes more overcharged at its lower end, and more undercharged at the upper end. Before this, every thing was juſt ready to ſnap. All will now ſtrike at once. The cloud will be diſcharged through the houſe, and the man will be the ſacrifice, the whole diſcharge being made through his body. This needs no demonſtration for any well-informed electrician. Thoſe who have only ſuch a knowledge of the theory as can be gathered from the writings of Prieſtley, Cavallo, and other popular authors, may convince themſelves of the truth of what is here delivered in the following manner.

In dry weather, and the moſt favourable circumſtances for good electrical experiments, let a very large globe,

Thunder.

globe, smoothly covered with metal, and well insulated, be as highly electrified as possible, without exposing it to a rapid dissipation. To ensure this circumstance (which is important) let it be electrified till it begins to sputter, and note the state of the electrometer. Discharge this electricity, and electrify it to about half of this intensity. Provide three or four insulated metal conductors, about three inches long and an inch diameter, terminated by hemispheres, and all well polished.

Having electrified the globe, as above directed, bring one of the insulated conductors slowly up to it, and note its distance when it receives a spark. In doing this, take care that there be no conducting body near the remote end of the insulated conductor. It will be best to push it gradually forward by means of a long glass rod. Withdraw the conductor, discharge its electricity, restore the globe to its former electricity, indicated by an electrometer, and repeat this experiment till the greatest striking distance is exactly discovered. Now set another of the insulated conductors about half an inch behind the first, and push them forward together, by a glass rod, till a spark is obtained. The striking distance will be found greater than before. Then repeat this last experiment, with this difference, that the two conductors are pushed forward by taking hold of the remote one. The striking distance will be found much greater than before. Lastly, push forward the two conductors, the remote one having a wire communicating with the ground, till they are a small matter *without* the striking distance; and, leaving them in this situation, take any little conducting body, such as a brass ball fixed on the end of a glass rod, and pass it briskly through between the globe and the nearest conductor, or through between the two conductors, taking care that it touch neither of them in the passage. It will be seen that, however swift the passage is made, there will be a discharge through all the four bodies. The inference from this is obvious and demonstrative.

A very remarkable instance of this fact was seen at the chapel in Tottenham Court Road, London. A man, going into the chapel by the east door, was killed by the thunder, which came down from the little bell-house, along the bell-wire, and the rod of the clock pendulum, from the end of which it leaped to some iron work above the door, and from thence, from nail to nail, till it reached the man's head.

This interruption of conduct, which is almost unavoidable in the construction of any building, is the cause of most of the accidents that are recorded; for when the ends of those communicating conductors are inclosed in materials of less conducting power, the electricity, in making its way to the next in a very dense state, never fails to explode every thing which can be converted into elastic vapour by heat. There is always a sufficient quantity of moisture in the stone or brickwork for this purpose; and most vegetable substances contain moisture or other expansible matter. The stone, brick, or timber, is burst, and thrown to a considerable distance; or if kept together by a weight of wall, the wall is shattered. It is worth remarking that although no force whatever seems able to prevent this explosion, the quantity of matter exploded is extremely small; for the stones are never thrown to a greater distance than they would have been by two or three grains of gunpowder properly confined.

All these accidents will be prevented by giving a sufficient uninterrupted conduct; and it is proper to make use of such a conductor, although it may invite many discharges which would not otherwise happen. So long as the conductor is sufficient for the purpose, there seems to be no doubt of the propriety of this maxim.

25 A thunder rod will protect even when it is not able to discharge the whole thunder.

But the most serious objection remains. As we are certain that these conductors, whether raised above the building or not, will produce discharges through them which otherwise would not have happened, and as we are quite uncertain whether the quantity contained in a thunder cloud may not greatly exceed what the thunder rod can conduct without being dissipated in smoke, it seems very dangerous thus to invite a stroke which our conductor may not be able to discharge. In particular, it is reasonable to believe that the strata of electrified clouds which come near the earth lose much of their electricity by passing over the sharp points of trees, &c. while those which are much higher may retain their electricity undiminished, and pass on. May it not therefore happen, that our conductor will invite a fatal stroke, which would have gone harmlessly by?

The doubt is natural, and it is important.

Let us suppose a very extensive and highly electrified cloud, in a positive state, to come within such a distance from a building as *just not to strike it*, if unprovided with a conductor, but which will most certainly strike the same building furnished with a conductor; and let the electricity be so great that the conductor shall be dissipated in smoke before even a small part of it is discharged—What will be the fate of the building? We believe that it will be perfectly safe.

However rapid we may suppose that motion by which electricity is communicated, it is still motion, and time elapses during the propagation. The cloud is discharged, not in a very instant, but in a very short time. Part of the cloud is therefore discharged, while it explodes the conductor, and the electricity of the remainder is now too weak (by our supposition) to strike the building no longer furnished with a conductor. This must be the case, however large and powerful the cloud may be, and however small the conductor.

But suppose that the cloud has come so near as to strike the building unprovided with a conductor. Then as much will be discharged through the building as it can conduct; and if the quantity be too great, the building will be destroyed: but let a conductor (tho' insufficient) be added. The discharge will be made through it as long as it lasts, and the remainder only will be discharged through the house, surely with much less danger than before.

The truth of these conclusions from theory is fully verified by fact. When the church of Newbury in New England was struck by lightning in 1755, a bell wire, no bigger than a knitting needle, conducted the thunder with perfect safety to the building as far down the steeple as the wire reached, though the stroke was so great that the wire had been exploded, and no part of it remained, but only a mark along the wall occasioned by its smoke. From the termination of the wire to the ground the steeple was exceedingly shattered, and stones of great weight were thrown out from the foundation (where they were probably moister) to the distance of 20 and 30 feet.

Another

Thunder.

'Another remarkable instance happened in the summer palace at St Petersburg. A Heyduk and a soldier of a foot regiment were standing centinels at the door of the jewel-chamber: the Heyduk, with his scimitar resting on his arm, was carelessly leaning on the soldier, who had his musket shouldered. Both were struck down with lightning; and the soldier was killed, his left leg scorched, and his shoes burst. The Heyduk had received no damage, but felt himself tripped up, as if a great dog had run against him. A narrow slip of gold lace, which was sewed along the seam of his jacket and pantaloon breeches, reaching to his shoes, had been exploded on the left side. This seems to have been his protection. In all probability, the stroke came to both along the musket (or perhaps to the Heyduk along the scimitar). The Heyduk had a complete, though insufficient, conductor, and was safe. The soldier had not, and was killed. The push felt by the former probably arose from the explosion of the lace.

It seems therefore plain that metalline conductors are always a protection; that advancing them above the building, increases their protection; and that pointing them may sometimes enable them to diminish a stroke, by discharging part of the electricity silently.

Dr Franklin having formed all his notions of thunder from his pre-established theory, and having seen the principal phenomena so conformable to it, was naturally led to expect this conformity in cases which he could not easily examine precisely by experiment. Accordingly, in his first dissertation, he affirmed that a fine point always discharges a thunder cloud silently, and at a great distance. The analogous experiments in artificial electricity are so beautiful and so perspicuous, that this confidence in the protecting power of fine points is not surprising: and this confidence was rendered almost complete by a most singular case which fell under his own observation He was awakened one night by loud cracks in his stair case, as if some person had been lashing the wainscoating with a great horsewhip. He thought it so, and got up in anger to chide the idle fool. On looking out at his chamber door, he saw that the disturbance proceeded from electric explosions at some interruptions of his conductor. He saw the electricity pass, sometimes in bright sparks, producing those loud thwacks, and sometimes in a long continued stream of dense white dazzling light as big as his finger, illuminating the stair-case like sunshine, and making a loud noise like a cutler's wheel. Had the cloud (says he) retained all this till it came within striking distance, the consequences would have been inconceivably dreadful. Yet not long after this he found that he had been in a mistake; for the house of Mr Watt in Philadelphia, furnished with a finely pointed conductor, was struck by a terrible clap of thunder, and the point of the conductor was melted down about two inches. This is perhaps the only instance on record of a finely-pointed *conductor* being struck. The board room at the powder magazine at Purfleet was indeed struck, though provided with a conductor; but the stroke was through another part of the building. St Peter's church, Cornhill, has been eight times struck between 1772 and 1787; while St Michael's, in its neighbourhood, and much higher, has never had a stroke since 1772, when it was furnished with an excellent pointed conductor by Mr Nairne.

Dr Franklin having seen the above exception to his rule, and reflected on it, acknowledges that there are cases where a pointed conductor may be struck, viz. when it serves as a stepping stone, to *complete* a canal of conveyance already near completed. A *small* cloud may sometimes serve as a stepping stone (like the man coming under a lustre) for the electricity to come out of a great cloud, and discharge through the pointed conductor. Whenever it comes to the striking distance from the conductor, it will explode at once; whereas the great cloud itself must have come nearer, and had its force gradually diminished. It is remarkable that a point, employed in this way in artificial electricity, must be brought nearer to another body than a ball need be, before it can receive a stroke. The difference is about one third of the whole. Nairne found, that a ball one nine tenths inches in diameter, exploded at the distance of nine inches, and a point at six inches distance.

29 A pointed conductor may sometimes be struck.

We must also observe that a pointed conductor can have no advantage over a blunt one in the case of a returning stroke; which is perhaps the most common of any. This depends on another discharge, which is made perhaps at a great distance. This was most distinctly the case in the instance mentioned some time ago, of the person at Vienna who had a shock from a thunder rod by an explosion far distant. This thunder rod was a very fine one, furnished with five gilt points.

30 Dr Franklin over-rated the protection of pointed conductors.

Still, however, this property of sharp points was greatly over-rated by Dr Franklin, and those who took all their notions of electricity from the simple discoveries of his sagacious mind. Unfortunately Dr Franklin had not cultivated mathematical knowledge; and, ever eager after discovery, and ardent in all his pursuits, his wonderful penetration carried him through, and seldom allowed him to rest long on false conclusions. He was certainly one of the greatest *philosophers*; and a little erudition would perhaps have brought him side by side with Newton. It was reserved, however, for Lord C. Cavendish and for Æpinus, to subject the investigations of Franklin to number and measure. By studying what they have written on the subject, or even the view which we have given of their theory in the article ELECTRICITY (*Suppl.*), the reader will be fully convinced, that a point has little or no advantage over a ball, with respect to a thunder cloud which is brought to the thunder rod by a brisk wind; although, when it comes slowly up during an almost perfect calm, it may discharge all that can be discharged without a snap. The constipation in a point is indeed very great, but the quantity constipated is moderate; and therefore its action, at any considerable distance, is but trifling. All this is fully verified by Dr Wilson's judicious experiments in the Pantheon. He had a prodigious quantity of electrified surface suspended there, and made a pointed apparatus come to its striking distance with a motion which he could regulate and measure. And he found that with the very moderate velocity of twelve feet in a second, he never failed of procuring a very smart stroke. The experiments made in the usual way by the partisans of sharp points (for it became a matter of indecent party) were numberless, and decidedly in their favour. The great and just authority of Dr Franklin, who was one of the committee, procured them still more consideration, or at least hindered people from seeing the force of Dr Wilson's reasoning. It is somewhat surprising.

prising, that Dr Wilson, a lover of mathematical learning, and a good judge, as appears from his publication of the papers of Mr Robins, did not himself see the full force of his own experiments. He had not surely studied either Æpinus or Cavendish. He indeed frequently says, that the state of the electricity in a thunder cloud, and in coated glass, is exceedingly different; and that the first extends its sensible influence much farther than the last, when both have the same quantity of electricity. But he seems not to have formed to himself any adequate notion of the difference. Had he done this, he would have seen that he has disposed his great electrified surface very improperly. It should have been collected much nearer his pointed apparatus, that this might, if possible, have been within the sphere of attraction of every part of his artificial cloud. He would then have found results, some of which would have been much more favourable to his own general opinion, while others would have exhibited the peculiarities of the sharp point in a more showy manner than any thing we have seen.

31 Thunder cloud very unlike coated glass;

Reasoning from the true theory of coated glass, we shall learn that, when the glass is exceedingly thin, the accumulation of electricity, or the charge, will be exceedingly great; while the external appearance, or apparent energy, of the electricity may be hardly sensible, and will extend to a very small distance. Thus, a circular plate of coated glass, six inches in diameter and one twentieth thick, when electrified so as to make an electrometer diverge 50 degrees, contains about 60 times as much electricity as a brass plate, of the same diameter, electrified to the same degree; and these two will have the same influence on an electrometer placed at a distance from them, and will give a spark nearly at the same distance. The spark from the coated glass will be bright, and will give a shock; while that from the brass plate will be trifling. The cause of the equality of influence is, that the positive electricity of the one side of the coated glass is almost balanced by the negative electricity of the other side, and the unbalanced part is about $\frac{1}{10}$th of the whole. If we now take a brass plate of $46\frac{1}{2}$ inches in diameter, and electrify it to the same degree with the coated glass, we shall find that it will require the same number of turns of the machine to bring it to this state, or to charge the coated glass. They contain the same quantity of electricity, and the spark of both will give the same shock. But this large plate will have a much wider influence: a person coming within ten feet of it will see his hair bend towards it, and feel like a cobweb on his face.

32 And the influence of sharp points is trifling.

It may be farther demonstrated that the power of a point to abstract the electricity to a given degree from the large plate, is vastly smaller than its power to abstract it to the same degree from the coated plate. This is different in the different degrees of the abstraction, and cannot be expressed by any one number.

All these considerations taken together, shew us that the pointed conductor has little advantage over the ball in the circumstance above-mentioned. It has, however, an advantage, and therefore should be employed; and in the case of a calm, or very gentle progress of the thunder cloud, the advantage may be very great.

33 An extensive and substantial metalline conductor is the chief security.

Thus we think the question decided; and the only remaining consideration is the quantity of metallic conduct that should be given. Prudence teaches us not to spare, especially in very lofty buildings. The conductor on the dome of St Paul's in London consists of four iron straps, each four inches broad and one half an inch thick. This conductor was once made red hot by a thunder stroke. No instance has been found of a rod one half an inch square being exploded. The accident at Mr Watt's house in Philadelphia is curious. The brass wire which terminated the rod had been ten inches long and one-fourth thick at the base, and two one-half inches were melted. It was unable, therefore, to conduct that stroke when its diameter was less than one-sixteenth of an inch.

We recommend lead or copper in preference to iron. Iron wastes by rust, and by exfoliating retains water, which may be dangerous by its expansion. A strap of lead, two inches broad and one fourth thick, stapled down to the roof or wall with brass staples, secures us from all risks from neglect. An iron rod, or one fastened with iron cramps, requires frequent inspection, to see that nothing has failed or wasted by rust. The point or points should surely be copper. It would be very proper to connect all the leads of the ridges, gutters, and spouts, with the conductor, by straps of lead. This will greatly extend its protection.

A great extent of building is not sufficiently secured by one conductor. And a powder magazine should have some erected round it at a distance on masts.

Maxims in a Thunder Storm.

Avoid being under trees—but be near them: do not avoid rain. When in a room, avoid the fire-side, which would bring you into the neighbourhood of the highest part of the house, viz. the stack of chimneys. The bell-wire, the grate, the fire irons are bad neighbours. Nay, the foot of the chimney is not a good one, especially if it has ever caked together by burning (A). Go to the middle of the room, and sit down, if not near a lustre, or any thing hanging from the ceiling. Avoid mirrors, or gilded mouldings.

Thunder Clouds, in physiology, are those clouds which are in a state fit for producing lightning and thunder. See the preceding article.

(A) In the terrible thunder stroke on Leven House in Scotland, the two great streams of electricity had taken the course of the vents which had been most in use, but not to get at the iron work, for it had branched off from the vents, at a great distance from the bottom. The chief conductors through the building had been various gilded mouldings, gilded leather hangings, gilded skreens, picture frames, and the foil of mirrors. In this progress the steps have been so many, and so capricious, that no line of progress can be traced, according to any principle. The thunder seems to have electrified at once the whole of the leaden roof, and, besides the two main tracks along the vents, to have afterwards darted at every metal thing in its way. The lowest point of the track was a leaden water cistern; which, however, received no damage; but a thick stone wall was burst through to get at it.

THUS, in sea-language, a word used by the pilot in directing the helmsman or steersman to keep the ship in her present situation when sailing with a scant wind, so that she may not approach too near the direction of the wind, which would shiver her sails, nor fall to leeward, and run farther out of her course.

TIBERIAS (anc. geog.), the last town of Galilee, situated on the south side of the lake Tiberias; built by Herod the Tetrarch, and called *Tiberias* in honour of the Emperor Tiberius; distant 30 stadia from Hippus, 60 from Gadara, and 120 from Scythopolis: whence it appears to have been at no great distance from where the Jordan runs out of the lake. It is a number of times mentioned by St John the Evangelist. Pliny places it on the west extremity of the lake, commending the salubrity of its hot waters. Jerome says, the ancient name was *Chenereth*; which, if true, will account for the name of the lake.

TIERRA DEL FUEGO, several islands at the southern extremity of America. They take their name from a volcano on the largest of them. They are all very barren and mountainous; but from what Mr Forster says, in his Voyage to the South Sea, the climate does not appear to be so rigorous and tempestuous as it is represented in Anson's Voyage. Upon the lower grounds and islands, that were sheltered by the high mountains, Mr Forster found several sorts of trees and plants, and a variety of birds. Among the trees was Winter's bark-tree, and a species of *arbutus*, loaded with red fruit of the size of small cherries, which were very well tasted. In some places there is also plenty of celery. Among the birds was a species of duck, of the size of a goose, which ran along the sea with amazing velocity, beating the water with its wings and feet. It had a grey plumage, with a yellow bill and feet, and a few white quill-feathers. At the Falkland islands it is called a *loggerhead-duck*. Among the birds are also plenty of geese and falcons. The rocks of some of the islands are covered with large muscle-shells, the fish of which is well flavoured. The natives of this country are short in their persons, not exceeding five feet six inches at most, their heads large, their faces broad, their cheek bones prominent, and their noses flat. They have little brown eyes, without life; their hair is black and lank, hanging about their heads in disorder, and besmeared with train-oil. On the chin they have a few straggling short hairs instead of a beard. The whole assemblage of their features forms the most loathsome picture of misery to which human nature can possibly be reduced. Those which Mr Forster saw had no other clothing than a small piece of seal skin, which hung from their shoulders to the middle of their back, being fastened round the neck with a string: the rest of their body was perfectly naked. Their natural colour seems to be an olive brown, with a kind of gloss, resembling that of copper; but many of them disguise themselves with streaks of red paint, and sometimes, though seldom, with white. Their whole character is a strange compound of stupidity, indifference, and inactivity. They have no other arms than bows and arrows; and their instruments for fishing are a kind of fish-gigs. They live chiefly on seals flesh, and like the fat oily part most. There is no appearance of any subordination among them; and their mode of life approaches nearer to that of brutes than that of any other nation.

TILLANDSIA, the large barren WILD PINE of the West Indies; a genus of the monogynia order, belonging to the hexandria class of plants. It is called *Caragatua* by Father Plumier, and is a parasitic plant, and ought perhaps, in strict propriety, to be denominated an *aquatic*: for although it is suspended in the air among the branches of lofty trees, to whose boughs it is fastened by its numerous roots; yet it is not indebted to those boughs, like the misletoe and other parasitic plants, for nourishment, but merely for support; provident Nature having, in a very extraordinary manner, supplied this with other means to preserve its existence: For the leaves, which much resemble those of the pine-apple, but are larger, surround this plant in a circular manner; each leaf being terminated near the stalk with a hollow bucket, which contains about half a pint of water. It is by these numerous small reservoirs of water that the roots, as well as every other part of this plant, are supplied with nourishment without the help of any earth. The flourishing condition of this plant, as well as the great growth of fig-trees, upon barren rocks, shews that water is of greater use to vegetation than earth.

One contrivance of Nature in this vegetable, says Dr Sloane, is truly admirable. The seed is crowned with many long downy threads, not only that it may be carried everywhere by the wind, but that by those threads, when driven through the boughs, it may be held fast, and stick to the arms and prominent parts of the barks of trees. So soon as it sprouts or germinates, although it be on the under part of a bough, its leaves and stalks rise perpendicular or erect: if they assumed any other direction, the cistern or reservoir just mentioned, made of the hollow leaves, could not hold water, which is necessary to the life and nourishment of the plant. In scarcity of water this reservoir is useful, not to the plant only, but to men, and even to birds and all sorts of insects, which come thither in troops, and seldom go away without refreshment.

To the same purpose, Dampier, in his Voyage to Campeachy, relates, "that the wild pine has leaves that will hold a pint and a half or quart of rain-water, which refreshes the leaves, and nourishes the roots. When we find these pines, we stick our knives into the leaves, just above the root; and the water gushing out, we catch it in our hats, as I myself have frequently done, to my great relief."

TIMÆUS, a Greek historian, the son of Andronicus, who was eminent for his riches and excellent qualities, was born at Tauromenium in Sicily, and flourished in the time of Agathocles. He wrote several books, and among the rest an history of his own country; but they are all lost.

TIMÆUS, a famous Pythagorean philosopher, was born at Locres in Italy, and lived before Plato. There is still extant a small treatise of his on Nature and the Soul of the World, written in the Doric dialect. This treatise, which is to be found in the works of Plato, furnished that great philosopher with the subject of his treatise intitled *Timæus*.

TINNING, the covering or lining of any thing with melted tin, or with tin reduced to a very fine leaf. Looking-glasses are foliated or *tinned* with thin plates of beaten tin, by a process described under the title FOLIATING, *Encycl.*

Kettles, sauce-pans, and other kitchen utensils, which are usually made of copper, are tinned by the following process: The surface to be tinned, if of new copper, should first be cleaned or scoured with salt and sulphuric acid (vitriolic acid) diluted with water. This, however, is not always done; some workmen contenting themselves with scouring it with sand perfectly dry, or with scales of iron. Powdered rosin is then strewed over it; and when the vessel or utensil is considerably heated, melted tin is poured into it, and rubbed with flax coiled hard over the surface to be coated. This tin may be either pure, such as that known by the name of *grain-tin*; or a composition consisting of two parts of tin and one of lead. For very obvious reasons, we should certainly prefer the pure tin; but the generality of workmen give the preference to the composition, because the surface coated with it appears more brilliant. The tin is not always put into the vessel in a liquid state; for some workmen strew it in small pieces over the surface to be coated, and then heat the vessel till the tin melt, when they rub it as formerly.

In tinning old vessels which have been tinned before, the process is somewhat different. In these cases, the surface is first scraped with an instrument proper for the purpose, or scoured with the scales of iron, which may be always found in a blacksmith's shop: it is then strewed over with sal ammoniac in powder, instead of rosin, or an infusion of sal ammoniac in stale urine is boiled in it till the urine be evaporated, and it is then tinned with pure tin; the composition of tin and lead being in this case never used. The tin, while liquid, is rubbed into the surface with a piece of sal ammoniac, instead of a bundle of flax. When iron vessels are to be tinned, they are first cleaned with muriatic acid, after which the process is the same as in the tinning of old copper.

In the year 1785, Mr John Poulain of Mortlake, Surrey, obtained a patent for the discovery of a new composition for tinning vessels, especially such as are used for culinary purposes. This composition consists of grain-tin one pound, good malleable iron one ounce and a half, platinum one drachm, silver one pennyweight, gold three grains: the whole must be well fused together in a crucible, with one ounce of pounded borax, and two ounces of pounded glass, and then cast in small ingots. The composition, to be fit for use, must be heated and put in a metal mortar, also heated over a fire, and well pounded with a heated metal pestle; when it is well pounded, make an ingot of it, by putting it on the fire in a mould made of iron plate, in which mould the composition must be well stirred and let to cool; then it is fit for use. To apply the composition, first tin the utensil or vessel with grain-tin and sal ammoniac, as is usually done in the common way of tinning; clean well the tinned part of the metal utensil or vessel, and then apply a coat of the composition with sal ammoniac, as is usually done in the common way of tinning; and when the composition is well spread, let it cool; then make it a little red-hot in all its parts, to neal it, and plunge the metal utensil or vessel, while yet hot, in cold water; then, with a sharp scraper, scrape and rub off the rough or grumous particles of the composition applied on the metal utensil or vessel, and scour it well with sand. The same operation must be repeated for every coat of the composition that is applied; two coats of the composition are quite sufficient for culinary utensils or vessels, and a thin coat of grain-tin may be applied over the last coat of the composition, to smooth it. The author adds, that his composition may be employed for covering or plating the surfaces of all materials made of copper, brass, iron, and other metals or mixtures of metals, and that it should be applied with a charcoal fire in preference to any other fire. All this may be true, and it may be a very valuable coating to copper; but the scarcity, high price, and infusibility of platinum, must for ever prevent it from coming into very general use.—We think that even the ENAMELLING *of Vessels for the Kitchen* must be more common. See that article in this *Supplement*.

The following process is less expensive, whilst the coating given by it is exceedingly durable, adds strength to the copper vessel, and secures it much longer than the common tinning from the action of acids:

When the vessel has been prepared and cleaned in the usual manner, it must be roughened on the inside by being beat on a rough anvil, in order that the tinning may hold better, and be more intimately connected with the copper. The process of tinning must then be begun with perfectly pure grained tin, having an addition of sal ammoniac instead of the common colophonium or resin. Over this tinning, which must cover the copper in an even and uniform manner throughout, a second harder coat must be applied, as the first forms only a kind of medium for connecting the second with the copper. For this second tinning you employ pure grained tin mixed with zinc in the proportion of two to three, which must be applied also with sal ammoniac smooth and even, so that the lower stratum may be entirely covered with it. This coating, which, by the addition of the zinc, becomes pretty hard and solid, is then to be hammered with a smoothing hammer, after it has been properly rubbed and scoured with chalk and water; by which means it becomes more solid, and acquires a smooth compact surface.

Vessels and utensils may be tinned in this manner on both sides. In this case, after being exposed to a sufficient heat, they must be dipped in the fluid tin, by which means both sides will be tinned at the same time.

As this tinning is exceedingly durable, and has a beautiful colour, which it always retains, it may be employed for various kinds of metal instruments and vessels which it may be necessary to secure from rust.

TINPLATE, called in Scotland *White-iron*, is a thin plate of iron covered with tin, to which it is united by chemical affinity. See CHEMISTRY, n° 122. *Suppl.*

TIPRA, the name of certain mountainous districts to the eastward of Bengal, inhabited by a people of very singular manners. As every thing which contributes a single fact to the history of human nature is interesting to the philosopher, the reader will be pleased with the following account of the religion, laws, and manners of these people, taken from the 2d volume of the *Asiatic Researches*.

Though they acknowledge one Creator of the universe, to whom they give the name of PA'TIYA'N, they believe that a deity exists in every tree, that the sun and moon are gods, and that whenever they worship those

subordinate divinities Pátiyán is placed. This is very similar to the religious creed of ancient Greece and Rome, differing only with respect to creation, which, in the proper sense of the word, the Greeks and Romans seem not to have admitted.

If any one of these mountaineers, called in the memoir Cucis, put another to death, the chief of the tribe, or other persons who bear no relation to the deceased, have no concern in punishing the murderer; but if the murdered person have a brother or other heir, he may take blood for blood; nor has any man whatever a right to prevent or oppose such retaliation.

When a man is detected in the commission of theft or other atrocious offence, the chieftain causes a recompense to be given to the complainant, and reconciles both parties; but the chief himself receives a customary fine, and each party gives a feast of pork or other meat to the people of his respective tribe.

In ancient times, it was not a custom among them to cut off the heads of the women whom they found in the habitations of their enemies; but it happened once that a woman asked another, why she came so late to her business of sowing grain? she answered, that her husband was gone to battle, and that the necessity of preparing food and other things for him had occasioned her delay. This answer was overheard by a man at enmity with her husband; and he was filled with resentment against her, considering, that as she had prepared food for her husband for the purpose of sending him to battle against his tribe, so in general, if women were not to remain at home, their husbands could not be supplied with provision, and consequently could not make war with advantage From that time it became a constant practice to cut off the heads of the enemy's women, especially if they happen to be pregnant, and therefore confined to their houses; and this barbarity is carried so far, that if a Cuci assail the house of an enemy, and kill a woman with child, so that he may bring two heads, he acquires honour and celebrity in his tribe, as the destroyer of two foes at once.

As to the marriages of this wild nation, when a rich man has made a contract of marriage, he gives four or five head of *gayáls* (the cattle of the mountains) to the father and mother of the bride, whom he carries to his own house: Her parents then kill the *gayáls*; and having prepared fermented liquors and boiled rice with other eatables, invite the father, mother, brethren, and kindred of the bridegroom to a nuptial entertainment. When a man of small property is inclined to marry, and a mutual agreement is made, a similar method is followed in a lower degree; and a man may marry any woman except his own mother. If a married couple live cordially together, and have a son, the wife is fixed and irremoveable; but if they have no son, and especially if they live together on bad terms, the husband may divorce his wife, and marry another woman.

They have no idea of heaven or hell, the reward of good, or the punishment of bad, actions; but they profess a belief, that when a person dies, a certain spirit comes and seizes his soul, which he carries away; and that whatever the spirit promises to give at the instant when the body dies, will be found and enjoyed by the dead; but that if any one should take up the corse and carry it off, he would not find the treasure.

The food of this people consists of elephants, hogs, deer, and other animals; of which if they find the carcases or limbs in the forests, they dry them, and eat them occasionally.

When they have resolved on war, they send spies, before hostilities are begun, to learn the stations and strength of the enemy, and the condition of the roads; after which they march in the night, and two or three hours before daylight make a sudden assault with swords, lances, and arrows: if their enemies are compelled to abandon their station, the assailants instantly put to death all the males and females, who are left behind, and strip the houses of all their furniture; but should their adversaries, having gained intelligence of the intended assault, be resolute enough to meet them in battle, and should they find themselves overmatched, they speedily retreat and quietly return to their own habitations. If at any time they see a star very near the moon, they say, "to-night we shall undoubtedly be attacked by some enemy;" and they pass that night under arms with extreme vigilance. They often lie in ambush in a forest near the path, where their foes are used to pass and repass, waiting for the enemy with different sorts of weapons, and killing every man or woman who happens to pass by: in this situation, if a leech, or a worm, or a snake, should bite one of them, he bears the pain in perfect silence; and whoever can bring home the head of an enemy, which he has cut off, is sure to be distinguished and exalted in his nation. When two hostile tribes appear to have equal force in battle, and neither has hopes of putting the other to flight, they make a signal of pacific intentions, and, sending agents reciprocally, soon conclude a treaty; after which they kill several head of *gayáls*, and feast on their flesh, calling on the sun and moon to bear witness of the pacification: but if one side, unable to resist the enemy, be thrown into disorder, the vanquished tribe is considered as tributary to the victors; who every year receive from them a certain number of *gayáls*, wooden dishes, weapons, and other acknowledgments of vassalage. Before they go to battle, they put a quantity of roasted *álus* (esculent roots like potatoes), and paste of riceflour, into the hollow of bamboos, and add to them a provision of dry rice with some leathern bags full of liquor: then they assemble, and march with such celerity, that in one day they perform a journey ordinarily made by letter-carriers in three or four days, since they have not the trouble and delay of dressing victuals. When they reach the place to be attacked, they surround it in the night, and at early dawn enter it, putting to death both young and old, women and children, except such as they choose to bring away captive: they put the heads, which they cut off, into leathern bags; and if the blood of their enemies be on their hands, they take care not to wash it off When after this slaughter they take their own food, they thrust a part of what they eat into the mouths of the heads which they have brought away, saying to each of them, "Eat, quench thy thirst, and satisfy thy appetite; as thou hast been slain by my hand, so may thy kinsmen be slain by my kinsmen!" During their journey, they have usually two such meals; and every watch, or two watches, they send intelligence of their proceedings to their families. When any one of them sends word that he has cut off the head of an enemy, the people of his family, whatever be their age or sex, express great de-

Tipra.

light, making caps and ornaments of red and black ropes; then filling some large vessels with fermented liquors, and decking themselves with all the trinkets they possess, they go forth to meet the conqueror, blowing large shells, and striking plates of metal, with other rude instruments of music. When both parties are met, they show extravagant joy, men and women dancing and singing together; and if a married man has brought an enemy's head, his wife wears a head dress with gay ornaments, the husband and wife alternately pour fermented liquor into each other's mouths, and she washes his bloody hands with the same liquor which they are drinking. Thus they go revelling, with excessive merriment, to their place of abode; and having piled up the heads of their enemies in the court yard of their chieftain's house, they sing and dance round the pile; after which they kill some *gayáls* and hogs with their spears; and having boiled the flesh, make a feast on it, and drink the fermented liquor. The richer men of this race fasten the heads of their foes on a bamboo, and fix it on the graves of their parents, by which act they acquire great reputation. He who brings back the head of a slaughtered enemy, receives presents from the wealthy of cattle and spirituous liquor; and if any captives are brought alive, it is the prerogative of those chieftains, who were not in the campaign, to strike off the heads of the captives. Their weapons are made by particular tribes; for some of them are unable to fabricate instruments of war.

In regard to their civil institutions; the whole management of their household affairs belongs to the women; while the men are employed in clearing forests, building huts, cultivating land, making war, or hunting game and wild beasts. Five days (they never reckon by months or years) after the birth of a male child, and three days after that of a female, they entertain their family and kinsmen with boiled rice and fermented liquor; and the parents of the child partake of the feast. They begin the ceremony with fixing a pole in the court yard; and then killing a *gayál* or a hog with a lance, they consecrate it to their deity; after which all the party eat the flesh and drink liquor, closing the day with a dance and with songs. If any one among them be so deformed, by nature or by accident, as to be unfit for the propagation of his species, he gives up all thought of keeping house, and begs for his subsistence, like a religious mendicant, from door to door, continually dancing and singing. When such a person goes to the house of a rich and liberal man, the owner of the house usually strings together a number of red and white stones, and fixes one end of the string on a long cane, so that the other end may hang down to the ground; then, paying a kind of superstitious homage to the pebbles, he gives alms to the beggar; after which he kills a *gayál* and a hog, and some other quadrupeds, and invites his tribe to a feast: the giver of such an entertainment acquires extraordinary fame in the nation, and all unite in applauding him with every token of honour and reverence.

When a *Cúci* dies, all his kinsmen join in killing a hog and a *gayál*; and, having boiled the meat, pour some liquor into the mouth of the deceased, round whose body they twist a piece of cloth by way of shroud: all of them taste the same liquor as an offering to his soul; and this ceremony they repeat at intervals for several days. Then they lay the body on a stage, and kindling a fire under it, pierce it with a spit and dry it; when it is perfectly dried, they cover it with two or three folds of cloth, and, enclosing it in a little case within a chest, bury it under ground. All the fruits and flowers that they gather within a year after the burial they scatter on the grave of the deceased: but some bury their dead in a different manner; covering them first with a shroud, then with a mat of woven reeds, and hanging them on a high tree. Some, when the flesh is decayed, wash the bones, and keep them dry in a bowl, which they open on every sudden emergence; and, fancying themselves at a consultation with the bones, pursue whatever measures they think proper; alleging that they act by the command of their departed parents and kinsmen. A widow is obliged to remain a whole year near the grave of her husband; where her family bring her food: if she die within the year, they mourn for her; if she live, they carry her back to her house, where all her relations are entertained with the usual feast of the *Cúcis*.

If the deceased leave three sons, the eldest and the youngest share all his property; but the middle son takes nothing: if he have no sons, his estate goes to his brothers; and if he have no brothers, it escheats to the chief of the tribe.

Tiresias, Tisri.

TIRESIAS, a famous soothsayer of antiquity, was the son of Everes and the nymph Chariclo. Pherecydes says, that Minerva being accidentally seen by Tiresias, as she was bathing with Chariclo in the fountain of Hippocrene, the goddess was enraged, and declared that he should see nothing more: on which he instantly lost his sight; but afterwards received from the goddess superior endowments. Others say, that Juno struck him stone-blind for deciding a case between Jupiter and her, to her dissatisfaction, for which Jupiter gave him the faculty of divination: He was the most celebrated prophet in the Grecian annals. Ulysses is ordered by Circe to consult him in the shades.

> There seek the Theban bard depriv'd of sight,
> Within irradiate with prophetic light.

But, besides the honour done to him by Homer, Sophocles makes him act a venerable and capital part in his tragedy of Oedipus. Callimachus ascribes to Minerva the gift of his superior endowments; the pre-eminence of his knowledge is likewise mentioned by Tully in his first book of Divination. And not only Tiresias is celebrated by Diodorus Siculus, but his daughter Daphne, who, like her father, was gifted with a prophetic spirit, and was appointed priestess at Delphos. She wrote many oracles in verse, from whence Homer was reported to have taken several lines, which he interwove in his poems. As she was often seized with a divine fury, she acquired the title of *sibyl*, which signifies "enthusiast" She is the first on whom it was bestowed: in aftertimes this denomination was given to several other females that were supposed to be inspired, and who uttered and wrote their predictions in verse; which verse being sung, their function may be justly said to unite the priesthood with prophecy, poetry, and music.

TISRI or TIZRI, in chronology, the first Hebrew month of the civil year, and the 7th of the ecclesiastical or sacred year. It answered to part of our September and October.

TITHING-MEN,

TITHING-MEN, are now a kind of petty constables, elected by parishes, and sworn in their offices in the court leet, and sometimes by justices of the peace, &c. There is frequently a tithing-man in the same town with a constable, who is, as it were, a deputy to execute the office in the constable's absence; but there are some things which a constable has power to do, that tithing-men and head-boroughs cannot intermeddle with. When there is no constable of a parish, his office and the authority of a tithing man seems to be all one under another name.

TITHONUS, in fabulous history, the son of Laomedon king of Troy, and the brother of Priamus; was beloved by Aurora, who carried him to Delos, thence to Ethiopia, and at last to heaven, where she prevailed on the Destinies to bestow upon him the gift of immortality; but forgot to add that of youth, which could only render the present valuable. At length Tithonus grew so old that he was obliged to be rocked to sleep like an infant; when Aurora, not being able to put an end to his misery by death, transformed him into a grasshopper; which renews its youth by casting his skin, and in its chirping retains the loquacity of old age.

TITLE FOR ORDERS, in the church of England, is an assurance of being employed and maintained as an officiating clergyman in some cathedral or parochial church, or other place of Divine worship. And, by the 33*d Canon*, "no one is to be ordained but in order to be a curate or incumbent, or to have some minister's place in some church, or except he be fellow, conduct, or chaplain, in some college in one of the universities, or be master of arts of five years standing, and live there at his own cost." By the same canon, the bishop who ordains a clerk without title, is bound to keep him till he prefer him to some ecclesiastical living.

TOD OF WOOL, is mentioned in the statute 12 Carol. II. c. 32. as a weight containing 2 stone, or 28 pounds.

TOMBUCTOO, a large city in North Africa, and capital of a kingdom of the same name. It has for some years past been the great object of European research, being one of the principal marts for that extensive commerce which the Moors carry on with the Negroes. The hopes of acquiring wealth in this pursuit, and zeal for propagating their religion, have filled this extensive city with Moors and Mahomedan converts; the king himself, and all the chief officers of state are Moors; and they are said to be more severe and intolerant in their principles than any other of the Moorish tribes in this part of Africa. Mr Park was informed, by a venerable old Negro, that when he first visited Tombuctoo, he took up his lodging at a sort of public inn, the landlord of which, when he conducted him into his hut, spread a mat on the floor, and laid a rope upon it; saying, "if you are a Mussulman, you are my friend, sit down; but if you are a Kafir, you are my slave; and with this rope I will lead you to market." The reigning sovereign of Tombuctoo, when Mr Park was in Africa, was named *Abu Abrahima*. He was reported to possess immense riches, and his wives and concubines were said to be clothed in silk, and the chief officers of state live in considerable splendour. The whole expence of his government is defrayed by a tax upon merchandize, which is collected at the gates of the city.

Of that city very little is known with accuracy, as it has never been visited by any European. It is the largest on the Niger, Houssa only excepted; and probably contains from 60,000 to 80,000 inhabitants. In some of the Gazetteers, its houses are said to be built in the form of bells; but they are probably such buildings as those of SEGO, which see in this *Supplement*. Tombuctoo, according to Major Rennel, is in 16′ 30′ N. Lat. and 1° 33′ E. Long. from Greenwich.

TOMSOOK, in the language of Bengal, a bond.

TOOTH-ACHE, a well known excruciating pain (see *Encycl.*), for the alleviation, and even the cure of which, many specifics have been offered to the public. Of one of the most extraordinary of these, there is an account, in a small work published at Florence in 1794, by professor Gerbi, who gives the description of an insect, a kind of *curculio*, which, from its property of allaying the tooth-ache, has received the epithet of *antiodontalgicus*, and which is found on a species of thistle, *carduus spinosissimus*. The flowers of this thistle, when analysed, gave the acid of galls, the muriatic acid, oxalat of lime, extractive matter, and a very little resin. On the bottom of the calyx, which supports the flowers, there are often found excrescences like the gall-nut, which are at first spheroidal, afterwards cylindric, and at length assume the figure of two hemispheres: they consist of the like component parts with the flowers, but contain more resin, and far more oxalat of lime; as the gall apple of the oak, according to the experiments of M. Branchi, which are here mentioned, contains more of the acid of galls than the bark and other parts of the oak, in which he could discover no sulphuric acid. The insect, according to the author's observations, eats not only the parenchyma, but also the vessels and fibres of the leaves. The egg, before the worm makes its appearance, is nourished by the sap of the plant, and of the above excrescences, in which it resides, by means of the attractive power that the egg possesses for certain vegetable juices and substances. The excrescences arise by the accumulation of a solid substance, which is precipitated from the nourishing juices of the thistle, diminished by nourishing the egg and the worm. This insect, the eggs of which are deposited in these excrescences, is, together with the *curculio* of the centaury, a new species. It is of a longish figure; covered below with short yellow hair, and above with golden yellow velvety spots. Its corslet is variegated with specks; and the covering of its wings with specks and stripes. It has a short proboscis, and shews some likeness to the *curculio villosus* of Geoffroy. Its larva represents a sort of ichneumon. By chemical analysis it exhibits some traces of common salt; by distillation with a strong dry heat, some volatile lixivious salts; and it contains, besides these, some gelatinous, and a little sebaceous and slimy extractive matter. If about a dozen or fifteen of these insects, when in the state of larva, or even when come to perfection, be bruised and rubbed slowly between the fore-finger and the thumb, until they have lost their moisture, and if the painful tooth, where it is hollow, be touched with that finger, the pain ceases, sometimes instantaneously. This power or property the finger will retain for a year, even though it be often washed and used. A piece of shamoy leather will serve equally well with the finger. Of 629 experiments, 401 were attended with complete success. In

Tooth-ache || Torelli.

two of these cases, the hollow teeth arose from some fault in the juices: in the rest they were merely local. If the gums are inflamed, the remedy is of no avail.

To the truth of this tale the reader will give what credit he pleases; but it is surely very difficult to believe, that a living finger, continually perspiring, can retain for a year the moisture imbibed from this insect. But it seems there are other insects which have the property of curing the tooth ache; such as the *carabus chrysocephalus* of Rossi; the *carabus ferrugineus* of Fabricius; the *coccinella septem punctata* (the lady bird); the *chrysomela populi*, and the *chrysomela sanguinolenta*. It would appear, therefore, that this property belongs to various kinds of the *coleoptera*.

The idea of these insects being endowed with the property of curing the tooth-ache is not confined to Italy; for Dr Hirsch, dentist to the court of Weimar, asserts (*Verkundiger*, September 24, 1798) that he employed them with the happiest effect, except in some cases where his patients were females. He says, that he took that small insect, found commonly among corn, *coccinella septem punctata*, and bruised it between his fingers. He then rubbed the fingers with which he had bruised it, till they became warm at the points, and touched with them the unsound parts of the gums, as well as the diseased tooth. Dr Hirsch adds, that he made the same experiment a few days after with equal success, though he had not bruised a new insect with his fingers. He seems to think that, to insure the efficacy of the process, the insect should be alive; because, when dead, its internal parts, in which he presumes the virtue chiefly resides, become dried up, leaving only the wings and an empty shell; and therefore proposes to physicians to turn their attention to the finding out of some method for preserving the virtue of the insect, so that its efficacy may be in full vigour throughout the year.

Besides these beetles, charcoal has been recommended as an anodyne in the tooth-ache; but whether it operates merely by filling the hollow of the tooth, and thereby preventing the access of atmospheric air to the nerve, or by any of its singular and hitherto unknown qualities, seems not to have been well ascertained.

TOR, a town of Asia, in Arabia Petræa, seated on the Red Sea, with a good harbour, defended by a castle. There is a handsome Greek convent, in whose garden are fountains of bitter water, which they pretend are those rendered sweet by Moses, by throwing a piece of wood into them. Some think that this town is the ancient Elana. E. Long. 31. 25. N. Lat. 28. 0.

TORELLI (Joseph), was born at Verona on the 4th of November 1721. His father Lucas Torelli, who was a merchant, dying while young Torelli was but an infant, he was left entirely to the care of his mother Antonia Albertini, a Venetian lady of an excellent character. After receiving the first rudiments of learning, he was placed under the Ballerini, who, observing the genius of the boy, prevailed upon his mother to send him to complete his education at Patavia. Here he spent four years entirely devoted to study, all his other pas- orbed by his thirst for knowledge.

l innocence of his life, and the prudenc and gravity of his conduct, soon attracting the atter tion of his masters, they not only commended him wi eagerness, but performed to him the part of parents, conversed with him familiarly about their respective sciences, and read over to him privately the lectures which they had to deliver. This was the case particularly with Hercules Dondinus, under whom Torelli studied jurisprudence. But he by no means confined himself to that science alone. The knowledge which he acquired was so general, that upon whatever subject the conversation happened to turn, he delivered his sentiments upon it in such a manner that one would have thought he had bestowed upon it his whole attention.

Torelli.

After receiving the degree of Doctor, he returned home to the enjoyment of a considerable fortune; which putting it into his power to choose his own mode of living, he determined to devote himself entirely to literary pursuits. He resolved, however, not to cultivate one particular branch to the exclusion of every oth but to make him self master of one thing after another, as his humour inclined him; and he was particularly attentive to lay an accurate and solid foundation. Tho' he declined practising as a lawyer, he did not, on that account, relinquish the study of law. The Hebrew, Greek, Latin, and Italian languages, occupied much of his time. His object was to understand accurately the two first, and to be able to write and speak the two last with propriety and elegance. Besides these languages, he learned French, Spanish, and English. On the last, in particular, he bestowed uncommon pains; for he was peculiarly attached to the British nation, and to British writers, whom he perused with the greatest attention; not merely to acquire the language, but to imbibe also that force and loftiness of sentiment for which they are so remarkable. Nay he even began an Italian translation of Paradise Lo

He likewise made himself acquainted with ethics, metaphysics, and polemic divinity; to which last subject he was induced to attention by the custom of his country. With an t history he was very familiarly acquainted, calli in to his assistance, while engaged in that study, aids of chronology, geography, and criticism. Thi art, indeed, by means of which what is counterfei ay be distinguished from what is genuine, what is erpolated from what is uncorrupted, and what is ellent from what is faulty, he carried about wit m as his counsellor and his guide on on all occasio f *music* he studied with attention, pre-

The theo owerful airs which make their way into ferring tho rouse the passions at the pleasure of the the soul, His knowledge of *pictures* was held in high musician by the artists themselves, who were accustom estimati his opinion concerning the fidelity of the ded to e harmony of colours, the value of the picture, sign, e name of the painter. He himself had a collecand not remarkably splendid indeed, but exceedingly tio chosen. *Architecture* he studied with still greater w ention, because he considered it as of more real utili- a

Nor did he neglect the pursuits of the *antiquarian*, ut made himself familiarly acquainted with coins, gems, medals, engravings, antique vessels, and monuments. Indeed scarce any monumental ins were engraved at Verona which he had not ...... composed or corrected. With the *antiquities* of his own country he was so intimately acquainted, that every person of emi- nence,

nence, who visited Verona, took care to have him in their company when they examined the curiosities of the city.

But these pursuits he considered merely as amusements; mathematics and the belles lettres were his serious studies. These studies are, in general, considered as incompatible; but Torelli was one of the few who could combine the gravity of the mathematician with the amenity of the muses and graces, and who handle the compass and the plectrum with equal skill. Of his progress in mathematics, several of his treatises, and especially his edition of Archimedes, published since his death by the university of Oxford, are sufficient proofs. Nor was his progress in the more pleasing parts of literature less distinguished. In both these studies he was partial to the ancients and was particularly hostile to the poetry and the literary innovations of the French.

Nothing could be purer or more elegant than his Latin style, which he had acquired at the expence of much time and labour. His Latin translation of Archimedes is a sufficient proof of this, and is indeed really wonderful, if we consider that the Romans, being far inferior to the Greeks in mathematical knowledge, their language was of necessity destitute of many necessary words and phrases. He wrote the Italian language with the classic elegance of the 14th and 15th centuries. Witness his different works in that language, both in prose and verse. H translated the whole of Æsop's Fables into Latin, and Theocritus, the *Epithalamium* of Catullus, and the *comed* of Plautus, called *Pseudolus*, into Italian verse. The wo first books of the Æneid were also translated by hi with such exactness, and so much in the style of the iginal, that they may well pass for the work of Virgil mself.

His life, like his studies, as drawn after the model of the ancient sages. Fr l, temperate, modest, he exhibited a striking contrast the luxurious manners of his age. In religion he ac d strictly, though not superstitiously, to the opinion f his ancestors. He was firm to his resolutions, but foolishly obstinate; and so strict an observer of eq that his probity would have remained inviolate, ev hough there had been no law to bind him to justice. e never married, that he might have leisure to devote self, with less interruption to his favourite studies. very one readily found admission to him, and no ma t him without being both pleased and instructed; h was the sweetness of his temper, and the readine ith which he communicated information. He adhere ith great constancy to his friendships. This was part rly exemplified in the case of Clemens Sibiliatus, w as favoured the world with the life of Torelli. W him he kept up the closest connection from a school- till the day of his death. He was peculiarly attache kewise to many men of distinction, both in Italy and ritain. He died in August 1781, in the 70th yea f his age.

The following is a complete list of his works, his e tion of Archimedes excepted, which was not publishe till after his death:

1. "Lucubratio Academica, sivi Somnium Jacobi Pindemontii, &c." Patavii, 1743.—2. "Animadversiones in Hebraicum Exodi Librum et in Græcum lxx Interpretationem;" Veronæ, 1744.—3. "De principe Gulæ incommodo, ejusque remedio, Libri duo;" Coloniæ Agrippinæ, 1744.—4. "De Probabili Vitæ Morumque Regula;" Coloniæ, 1747.—5. "Li due primi Canti dell' Iliade (di Scipione Maffei) e li due primi dell' Eneide di Giuseppe Torelli tradotti in versi Italiani;" Verona, 1749.—6. "Gli stessi due canti dell' Eneide ristampati soli lo stesso anno per lo stesso Ramanzini"—7. "Scala de Meriti a capo d'anno Trattato Geometrico;" Verona, 1751.—8. "De Nihilo Geometrico, lib. 2.;" Veronæ, 1758.—9. "Lettera intorno a due passi del Purgatorio di Dante Alighiero;" *ib* 1760.—10. "Della Denominazione del corrente anno volgarmente detto 1760 in Bologna per Lelio della Volpe." 11. "Il pseudolo. Comedia. &c e si aggiunge la traduzione d'alcuni Idilli di Teocrito e di Mosco;" Firenze, 1765—12. "Inno a Maria Virgine nella Festivita della sua Concezione;" Verona, 1766.—13. "Lettera a Miladi Vaing-Reit premessa al libro che ha per titalo xii. lettere Inglesi, con altra lettera all'autore della suddetta;" Verona, 1767.—14. "Elegia di Tommaso Gray, Poeta Inglese, in un Cimetero Campestre in versi Italiani rimati;" Verona, 1767.—15. "Geometrica;" Veronæ, 1769—16. "Demonstratio antiqui Theorematis de motuum commixtione;" Veronæ, 1774.—17. "Lettera supra Dante contro il Signor di Voltaire;" Verona, 1781.—18. "Poemetto di Catullo su le Nozze di Peleo e Tetite, ed un Epitalamio dello stesso;" 1781.—19. "Œsopi Fabulæ."—20. "Teocrito tradotto, in versi Toscani."—21. "Elementi d'Euclide tradotti nell'idioma Italiano."—22. "Elementorum Prospectivæ, libri duo."

TORPEDO, or CRAMP-FISH, has been described under the generic title RAJA; and an attempt made to explain its electrical phenomena in the article ELECTRICITY, n° 258, &c. (Both these articles are in the *Encyclopædia*). From some late discoveries, however, of Volta and others, the shock given by the torpedo appears much more analogous to the shock of GALVANISM than to that of common electricity; and even the electrical organs of the fish seem to resemble the apparatus with which those discoveries in galvanism were made.

In the 63d volume of the Philosophical Transactions, Mr Hunter describes the electric organ of the torpedo as consisting of a number of columns, varying in their length from an inch and a half to a quarter of an inch, with diameters about two-tenths of an inch. The number of columns in each organ of the torpedo which he presented to the Royal Society was about 470; but in a very large torpedo which he dissected, the number of columns in one organ was 1182. These columns were composed of films parallel to the base of each; and the distance between each partition of the columns was $\frac{1}{150}$th of an inch. From these facts, the reader will find the anomalies of torpedinal electricity (supposing it the same with common electricity) accounted for in a very ingenious and philosophical manner by Mr Nicholson, at p. 358 of the first volume of his valuable Journal. We pass on, however, to point out the resemblance between it and the lately discovered phenomena in galvanism.

Take any number of plates of copper, or, which is better, of silver, and an equal number of tin, or, which is much better, of zinc, and a like number of discs, or pieces

Torpedo.

pieces of card, or leather, or cloth (A), or any porous subſtance capable of retaining moiſture. Let theſe laſt be ſoaked in pure water, or, which is better, ſalt and water, or alkaline leys. The ſilver or copper may be pieces of money. Build up a pile of theſe pieces; namely, a piece of ſilver, a piece of zinc, and a piece of wet card: then another piece of ſilver, a piece of zinc, and a piece of wet card: and ſo forth, in the ſame order (or any other order, provided the pieces ſucceed each other in their turn), till the whole number intended to be made uſe of is builded up. The inſtrument is then completed.

In this ſtate it will afford a perpetual current of the galvanic influence through any conductor communicating between its upper and lower plates; and if this conductor be an animal, it will receive an electrical ſhock as often as the touch is made, by which the circuit is completed. Thus if one hand be applied to the lower plate, and the other to the upper, the operator will receive a ſhock, and that as often as he pleaſes to lift his finger and put it down again.

This ſhock reſembles the weak charge of a battery of immenſe ſurface; and its intenſity is ſo low that it cannot make its way through the dry ſkin. It is therefore neceſſary that a large ſurface of each hand ſhould be well wetted, and a piece of metal be graſped in each, in order to make the touch; or elſe that the two extremities of the pile ſhould communicate with ſeparate veſſels of water, in which the hands may be plunged.

The commotion is ſtronger the more numerous the pieces. Twenty pieces will give a ſhock in the arms, if the above precautions be attended to. One hundred pieces may be felt to the ſhoulders. The current acts on the animal ſyſtem while the circuit is complete, as well as during the inſtant of commotion, and the action is abominably painful at any place where the ſkin is broken.

That this influence, whatever it may be, has a ſtriking reſemblance to the repeated ſhocks given by the torpedo, is obvious; but what it really is in itſelf muſt be aſcertained, if it can be aſcertained at all, by future experiments. Mr Nicholſon indeed, from whoſe Journal we have taken this account of Volta's apparatus and its effects, ſeems confident that theſe effects proceed from an electrical ſtream or current; but this mode of operation is quite foreign from all the laws of electricity known to us. The galvanic influence in this apparatus appears to move perpetually in a circle; to which we are acquainted with no fact in electricity that is at all ſimilar. Galvaniſm, too, ſeems capable of accumulation, even while ſurrounded by conducting ſubſtances, which is quite inconſiſtent with all that we *diſtinctly* know of electricity and its laws.

That the energy of the apparatus, however, is the effect of an electric ſtream or current, our ingenious author thinks proved by the condenſer with which Sig. Volta aſcertained the kind of the electricity, and obtained its ſpark. He finds the action ſtrongeſt, or moſt pungent, on wounds on the minus ſide of the apparatus, or where the wounds give out electricity; a fact alſo obſervable in the common electric ſpark.

The theory of the learned inventor ſeems to be, that it is a property of ſuch bodies as differ in their power of conducting electricity, that when they are brought into contact they will occaſion a ſtream of the electric matter. So that if zinc and ſilver be made to communicate immediately by contact, there will be a place of good conducting energy; and if they be made to communicate mediately by means of water, there will be a place of inferior conducting energy: and wherever this happens, there will be a ſtream or current produced in the general ſtock of electricity. This is not deduced as the conſequence of other more ſimple facts; but is laid down as a general or ſimple principle grounded on the phenomena. If ſo, is it not a *petitio principii?* That ſuch bodies as zinc and ſilver, when properly diſpoſed, produce a ſtream or current, or ſomething analogous to a ſtream or current, in the galvanic fluid, follows indeed indiſputably from the phenomena; but it by no means follows from the ſame phenomena that galvaniſm is electricity; for electricity ſeems ſubject to different laws. See ELECTRICITY and THUNDER, both in this *Supplement*.

It muſt be acknowledged that the diſcovery of the galvanic ſhock and ſpark, and of the apparent exiſtence of two oppoſite ſtates of galvaniſm correſponding to poſitive and negative electricity, conſiderably increaſe the analogy; which, in the article GALVANISM, *Suppl.* we have admitted to be very ſtriking: but ſuppoſing no fallacy in any of Volta's experiments, we do not think that theſe diſcoveries amount to any thing like a demonſtration of the concluſions which have been drawn from them. It is by no means certain that light is eſſentially connected with the electric fluid; for we know that it is not eſſentially connected with heat: (See *THERMOMETRICAL Spectrum*, in this *Suppl.*) The flaſh, for example, of lightning may be merely an extrication of light, in conſequence of the action of electricity upon the atmoſphere in its paſſage, or on the bodies upon which it impinges; and there are many inſtances of a ſimilar extrication, as in the colliſion of two pieces of flint, where neither electricity nor galvaniſm were ever ſuſpected to have any ſhare in producing the phenomenon. Why may not the progreſs of the galvanic fluid have a ſimilar effect in this inſtance with that of electricity, though the two fluids be eſſentially different between themſelves? But we have more to ſay on this ſubject.

Meſſrs Nicholſon and Carliſle conſtructed an apparatus ſimilar to that of Volta, which gave them a ſhock as before deſcribed, and a very acute ſenſation wherever the ſkin was broken. Their firſt reſearch was directed to aſcertain that the ſhock they felt was really an electrical phenomenon. For this purpoſe the pile was placed upon Bennett's gold leaf electrometer, and a wire was then made to communicate from the top of the pile to the metallic ſtand or foot of the inſtrument; ſo that the circuit of the ſhock would have been thro' the leaves, if they had diverged; but no ſigns of electricity appeared. Recourſe was then had to the revolving doubler; of which the reader will find an account in our Supplementary article ELECTRICITY,

(A) Woollen or linen cloth appear to be more durable, and more ſpeedily ſoaked, than card.

n° 202. The doubler had been previously cleared of electricity by twenty turns in connection with the earth. The negative divergence was produced in the electrometer. Repeated experiments of this kind shewed that the silver end was in the minus, and the zinc end in the plus state.

Here a pile of 17 half crowns, with a like number of pieces of zinc, and of pasteboard soaked in salt water, though it gave a severe shock, exhibited no symptoms of electricity till assisted by the doubler. Will it be said that this arose from want of intensity in the galvanic shock? We can only reply, that a much less intense shock of electricity would have produced a sensible divergence in the instrument without the doubler. What was the cause of this difference? We have, however, no doubt but that electricity was concerned in this phenomenon, for we have shewn elsewhere (see THUNDER, *Suppl.*), that either *electricity* is produced, or the equilibrium of the electrical fluid disturbed, by every chemical solution; and we shall see immediately that chemical solutions are perpetually going on in Volta's apparatus.

Very early in the course of this experiment, the contacts being made sure by placing a drop of water upon the upper plate, Mr Carlisle observed a disengagement of gas round the touching wire. This gas, though very minute in quantity, evidently seemed to have the smell afforded by hydrogen when the wire of communication was steel. This, with some other facts, led Mr Nicholson to propose to break the circuit by the substitution of a tube of water between two wires. They therefore inserted a brass wire through each of two corks inserted in a glass tube of half an inch internal diameter. The tube was filled with New River water, and the distance between the points of the wires in the water was one inch and three quarters. This compound discharger was applied so that the external ends of its wire were in contact with the two extreme plates of a pile of 36 half crowns, with the correspondent pieces of zinc and pasteboard. A fine stream of minute bubbles immediately began to flow from the point of the lower wire in the tube which communicated with the silver, and the opposite point of the upper wire became tarnished, first deep orange, and then black. On reversing the tube, the gas came from the other point, which was now lowest; while the upper, in its turn, became tarnished and black. Reversing the tube again, the phenomena again changed their order. In this state the whole was left for two hours and a half. The upper wire gradually emitted whitish filmy clouds, which, towards the end of the process, became of a pea green colour, and hung in perpendicular threads from the extreme half inch of the wire, the water being rendered semi-opaque by what fell off, and in a great part lay, of a pale green, on the lower surface of the tube, which, in this disposition of the apparatus, was inclined about forty degrees to the horizon. The lower wire, of three quarters of an inch long, constantly emitted gas, except when another circuit, or complete wire, was applied to the apparatus; during which time the emission of gas was suspended. When this last mentioned wire was removed, the gas re-appeared as before, not instantly, but after the lapse of four beats of a half second clock standing in the room. The product of gas, during the whole two hours and a half, was two-thirtieths of a cubic inch. It was then mixed with an equal quantity of common air, and exploded by the application of a lighted waxed thread.

Messrs Nicholson and Carlisle had been led, by their reasoning on the first appearance of hydrogen, to expect a decomposition of the water; but it was with no little surprize that they found the hydrogen extricated at the contact with one wire, while the oxygen fixed itself, in combination with the other wire, at the distance of almost two inches. This new fact still remains to be explained, and seems, says Mr Nicholson, to point at some general law of the agency of electricity in chemical operations. Does it not as naturally suggest a suspicion that galvanism is not electricity; especially as we are informed, by Mr Cruickshank of Woolwich, that Messrs Nicholson and Carlisle discovered, that "galvanism decomposes water with much greater facility than electricity, and with phenomena somewhat different?" What the particular differences are, he does not say; but we learn from Mr Nicholson himself, that from the general tenor of his experiments, it appears to be established, that the decomposition of water by galvanism is more effectual the less the distance is between the wires, but that it ceases altogether when the wires are in contact.

Mr Nicholson concludes his memoir with mentioning concisely the effects of a pile of 100 half crowns, and a chemical incident, which appears to be the most remarkable of those which he has yet observed.

The pile was set up with pieces of green woollen cloth soaked in salt water. It gave severe shocks, which were felt as high as the shoulders. The transition was much less forcible through a number of persons, but it was very perceptible through nine. The spark was frequently visible when the discharge was made in the dark, and a gleam of light was also, in some instances, seen about the middle of the column at the instant of the explosion. The assistants were of opinion that they heard the snap.

The extrication of the gases was rapid and plentiful by means of this apparatus. When copper wires were used for the broken circuit, with muriatic acid diluted with 100 parts of water in the tube, no gas, nor the least circulation of the fluid was perceived, when the distance of the wires was two inches. A short tube, with two copper wires very near each other in common water, was made part of the circuit, and shewed, by the usual phenomena, that the stream of electricity was rapidly passing. The wires in the muriatic acid were then slided within the third of an inch of each other. For the sake of brevity he avoids enumerating the effects which took place during several hours, and simply states, that the minus wire gave out some hydrogen during an hour; while the plus wire was corroded, and exhibited no oxyd; but a deposition of copper was formed round the minus, or lower wire, which began at its lower end: that no gas whatever appeared in this tube during two hours, though the deposition was going on, and the small tube shewed the continuance of the electric stream; and that the deposition, at the end of four hours, formed a ramified metallic vegetation, nine or ten times the bulk of the wire it surrounded.

In this experiment, it appeared that the influence of electricity increasing the oxydability of the upper wire, and affording nascent hydrogen from the lower, caused the

the latter to act as the precipitant of a solution of one and the same metal.

Mr Nicholson, we see, continues to call it electricity with the utmost confidence, as if it could not possibly be any thing else; and yet he says that the galvanic shock is much less forcible when passed through a number of persons than when passed only through one. This, we believe, does not hold in the shocks of common electricity; and the difference probably arises from the cuticle obstructing the passage of the one and not of the other. Volta himself says, that *this* electricity, for he too is desirous to prove it electricity, does not diffuse itself through the air. It is so universally known that very dry air is no conductor of electricity, that he must mean, on this occasion, air not uncommonly dry; otherwise the non diffusion of *this* electricity through air would not distinguish it, as he seems to admit it does, from common electricity. But what occasions this distinction, if the two electricities be the same?

Lieutenant-colonel Haldane, well known in the scientific world, made experiments with Volta's pillar, both in a horizontal and in a vertical position. With a large pillar, placed vertically, he obtained very weak signs of electricity. He connected the apparatus with the conductor of an electrical machine, and found the effect rather impeded than assisted by the common electric stream. He placed the plate of Bennet's electrometer in the circuit, without producing electric signs. He found that the galvanic apparatus, placed between the outside and inside of a jar, prevented its charging, and that it is also capable of conducting the charge, though not rapidly: and, on the whole, from the very minute exhibition of the attractive and repellent powers, while the causticity, the shock, and the oxydation, are so very powerful, he cannot be persuaded that electricity is the principal agent, though some might be generated, or disengaged, during the operation of the apparatus.

This is exactly our own opinion, which is strongly corroborated by the results of some very curious experiments made by Mr Cruickshank of Woolwich. These experiments our limits permit us not to detail. They were made with a view to ascertain the nature and relative proportions of the gases obtained from water and other fluids by this influence; and the author thinks himself authorised to conclude from them:

1. That hydrogen gas, mixed with a very small proportion of oxygen and ammonia, is somehow disengaged at the wire connected with the silver extremity of the machine; and that this effect is equally produced, whatever the nature of the metallic wire may be, provided the fluid operated upon be pure water.

2. That where metallic solutions are employed instead of water, the same wire which separates the hydrogen revives the metallic calx, and deposits it at the extremity of the wire in its pure metallic state; in this case no hydrogen gas is disengaged. The wire employed for this purpose may be of any metal.

3. That of the earthy solutions, those of magnesia and argil only are decomposed by the silver wire; a circumstance which strongly favours the production of ammonia.

4. That when the wire connected with the zinc extremity of the pile consists either of gold or platinum, a quantity of oxygen gas, mixed with a little azote and nitrous acid, is disengaged; and the quantity of gas thus obtained is a little better than $\frac{1}{3}$d of the hydrogen gas separated by the silver wire at the same time.

5. That when the wire connected with the zinc is silver, or any of the imperfect metals, a small portion of oxygenous gas is likewise given out; but the wire itself is either oxydated or dissolved, or partly oxydated and partly dissolved: indeed, the effect in this case produced upon the metal is very similar to that of the concentrated nitrous acid, where a great deal of the metal is oxydated, and but a small quantity held in solution.

6. That when the gases obtained by gold or platinum wires are collected together and exploded over mercury, the whole nearly disappears and forms water, with probably a little nitrous acid; for there was always a thick white vapour perceived for some time after the explosion. The residuary gas, in this case, appeared to be azote.

In reflecting on these experiments, it would appear that in some of them the water must be decomposed: but how this can be effected is by no means so easily explained. For example, it seems extremely mysterious how the oxygen should pass silently from the extremity of the silver wire to that of the zinc wire, and there make its appearance in the form of gas. It is to be observed, likewise, that this effect takes place which ever way the wires are placed, and whatever bends may be interposed between their extremities, provided the distance be not too great. On considering these facts more minutely, it appeared to Mr Cruickshank that the easiest and simplest mode of explanation would be, to suppose that the galvanic influence (whatever it may be) is capable of existing in two states, that is, in an oxygenated and deoxygenated state; that when it passes from metals to fluids containing oxygen, it seizes their oxygen, and becomes oxygenated; but when it passes from the fluid to the metal again, it assumes its former state, and becomes deoxygenated. Now when water is the fluid interposed, and the influence enters it from the silver side deoxygenated (and we suppose that it always passes from the deoxygenated to the oxygenated side), it seizes the oxygen of the water, and disengages the hydrogen, which accordingly appears in the form of gas; but when the influence enters the zinc wire, it parts with the oxygen, with which it had formerly united; and this either escapes in the form of gas, unites with the metal to form an oxyd, or, combined with a certain portion of water, &c. may, according to the German chemists, form nitrous acid. When a metallic solution is the interposed fluid, the effect produced may be explained in two ways; but the simplest is to suppose that the influence, in passing from the silver wire, seizes the oxygen of the metallic calx, and afterwards deposits it on entering the zinc one. In this case no gas should appear at the silver wire; but when a perfect metal is employed, oxygen should be disengaged from the zinc wire: and this, as has been already mentioned, is exactly what takes place.

What our author considers as the strongest argument in favour of this hypothesis, and what we consider as an argument equally strong to prove that galvanism differs essentially from electricity, is, that all fluids which do not contain oxygen, are incapable of transmitting the galvanic fluid, such as alcohol, æther, the fat

effential oils, as he has proved by direct experiment; but on the contrary, that all thofe which do contain oxygen conduct it more or lefs readily, as all aqueous fluids, metallic folutions, and acids, more efpecially the concentrated fulphuric acid; which it decompofes. In this laft inftance, the oxygen produced can hardly be afcribed to the decompofition of water; for this acid, when properly concentrated, does not contain any fenfible quantity. By this theory alfo we can readily explain the oxydation of the zinc plates in the machine; where the fluid in paffing from the different pairs of plates appears to be alternately oxygenated and deoxygenated. Although I am not (fays Mr Cruikfhank) by any means entirely fatisfied with this bypothefis, yet as it is the only one by which I can explain the different phenomena, it was thought advifable to throw it out, merely with a view to induce others to reafon upon the fubject, and to incite them to make experiments, by which alone truth can be afcertained.

We approve heartily of his conduct. It is for the fame reafon, and not to maintain at all hazards any preconceived opinion of our own, that we have urged every objection that occurs to us againft the hypothefis of the identity of galvanifm and electricity. Thefe fluids or influences appear to us to differ effentially; but ftill we admit that future experiments and future reafonings *may remove* our objections, which, however, ought never to be loft fight of *till* they be removed. If ingenious men, adopting implicitly the hypothefis of Volta and Mr Nicholfon, fhall inftitute a fet of experiments to afcertain the laws of the galvanic influence, they will be very apt to make their experiments fupport their hypothefis, inftead of employing them as guides to the temple of truth. Mr Nicholfon fays, that in all the experiments made by him and Mr Carlifle, the action of the inftrument was freely tranfmitted through the ufual conductors of electricity (meaning, we fuppofe, metals and watery fluids), but that it was ftopped by glafs and other non-conductors. We have experienced the fame thing, and fo far we acknowledge a ftriking refemblance between galvanifm and electricity; but, on the other hand, we have never been able to make any accumulation of galvanifm by means of coated electrics, whilft Mr Cruickfhank found that the galvanic influence cannot be tranfmitted through alcohol, ether, or effential oils. In thefe inftances, the difference between galvanifm and electricity feems to be as ftriking as the refemblance is in the others. Indeed thefe differences between the one and the other are fo many and fo great, that M. Fabbroni attributes the phenomena of galvanifm not to electricity, but to a chemical operation; to the tranfition of oxygen into a combination, and to the formation of a new compound. He had obferved, in repeating the common experiment, that if he wiped his tongue as accurately as poffible, the fenfation of tafte excited by the two metals was fo diminifhed as to be hardly diftinguifhed. The faliva, or fome other moifture, muft therefore be of fome importance in this phenomenon. He afterwards inftituted a fet of very proper experiments; from which it appeared to him that an evident chemical action takes place in the operations of galvanifm, and that it is unneceffary to feek farther for the nature of the new ftimulus. Galvanifm (he fays) is manifeftly a combuftion or oxydation of the metals; and the ftimulating principle may be either the caloric which is difengaged, or the oxygen which paffes into new combinations; or the new metallic falt; but which of thefe he has not afcertained.

Without adopting or rejecting thefe conclufions, we recommend them to the attention of our chemical readers; for it is only by expert and fcientific chemifts that we expect the nature and properties of galvanifm to be afcertained. In the mean time, it is proper to obferve, that the pile of Volta continues in order for about three days, and fcarcely three; and that on account of the corrofion of the fæces of the zinc, it is neceffary to renew them previous to each conftruction of the pile. This may be done by fcraping or grinding, or by cleaning them with diluted muriatic acid.

To avoid the trouble of conftantly repiling the pieces of filver and zinc, Mr Cruickfhank conftructed a kind of trough of baked wood, 26 inches in length, 1.7 inches deep, and 1.5 inches wide; in the fides of this trough grooves were made oppofite to each other, about the tenth of an inch in depth, and fufficiently wide to admit one of the plates of zinc and filver when foldered together; three of thefe grooves were made in the fpace of one inch and three tenths, fo that the whole machine contained 60 pair of plates. A plate of zinc and filver, each 1.6 inches fquare, well cemented together, were introduced into each of thefe grooves or notches, and afterwards cemented into the trough by a compofition of rofin and wax, fo perfectly that no water could pafs from one cell to the other, nor between the plates of zinc and filver. This circumftance muft be ftrictly attended to, elfe the machine will be extremely imperfect. When all the plates were thus fecured in the trough, the interftices or cells formed by the different pairs of plates were filled with a folution of the muriat of ammonia, which here fupplied the place of the moiftened papers in the pile, but anfwered the purpofe much better. It is hardly neceffary to obferve, that in fixing the zinc and filver plates, they muft be placed regularly, as in the pile, *viz.* alternately zinc and filver, the filver plate being always on the fame fide. When a communication was made between the firft and laft cell, a ftrong fhock was felt in the arms, but fomewhat different from that given by the pile, being quicker, lefs tremulous, and bearing a greater refemblance to the common electrical fhock. He conftructed two of thefe machines, which contained in all 100 pair of plates; thefe when joined together gave a very ftrong fhock, and the fpark could be taken in the day-time at pleafure; but what furprifed him not a little, was the very flender power which they poffeffed in decompofing water: in this refpect they were certainly inferior to a pile of 30 pair, although fuch a pile would not give a fhock of one third the ftrength.

This apparatus retained its power for many days, and would in all probability have retained it much longer, had not the fluid got between the dry furfaces of the metals. To remedy this defect, he foldered the zinc and filver plates together, and found that this method anfwers very well. The zinc plates may be cleaned at any time, by filling the different cells for a few minutes with the dilute muriatic acid. Although this apparatus may not entirely fuperfede the pile, efpecially if it fhould be found to decompofe water, &c. but flowly, yet in other refpects it will no doubt be found very convenient and portable.

If this article be thought long, and if we appear to have loft fight of our original fubject, the *Torpedo*, we

have only to plead in excuse for our conduct, that whilst we could not avoid pointing out the resemblance between the shock given by the torpedo and that by Volta's apparatus, we felt it a kind of duty to embrace the only opportunity that we shall have of laying before our readers the additional information respecting the phenomena of GALVANISM which we have received since the publication of that article. These phenomena are yet new, and they are unquestionably important; indeed so very important, that to us it appears neither impossible, nor even improbable, that to the galvanic agency of metals and minerals may be attributed volcanoes and earthquakes.

TOUCAN, or AMERICAN GOOSE, is one of the modern constellations of the southern hemisphere, consisting of nine small stars.

TRACTRIX, in geometry, a curve line, called also CATENARIA; which see, *Encycl.* and ARCH, *Suppl.*

TRADESCANT (John), an ingenious naturalist and antiquary, was, according to Anthony Wood, a Fleming or a Dutchman. We are informed by Parkinson, that he had travelled into most parts of Europe, and into Barbary; and from some emblems remaining upon his monument in Lambeth church-yard, it plainly appears that he had visited Greece, Egypt, and other eastern countries. In his travels, he is supposed to have collected, not only plants and seeds, but most of those curiosities of every sort which, after his death, were sold by his son to the famous Elias Ashmole, and deposited in his museum at Oxford. When he first settled in this kingdom cannot, at this distance of time, be ascertained. Perhaps it was at the latter end of the reign of Queen Elizabeth, or the beginning of that of King James I. His print, engraven by Hollar before the year 1656, which represents him as a person very far advanced in years, seems to countenance this opinion. He lived in a great house at South Lambeth, where his museum was frequently visited by persons of rank, who became benefactors thereto: among these were King Charles I. (to whom he was gardener), Henrietta Maria his Queen, Archbishop Laud, George Duke of Buckingham, Robert and William Cecil, Earls of Salisbury, and many other persons of distinction. John Tradescant may therefore be justly considered as the earliest collector (in this kingdom) of every thing that was curious in natural history, viz. minerals, birds, fishes, insects, &c. He had also a good collection of coins and medals of all sorts, besides a great variety of uncommon rarities. A catalogue of these, published by his son, contains an enumeration of the many plants, shrubs, trees, &c. growing in his garden, which was pretty extensive. Some of these plants are, if not totally extinct, at least become very uncommon, even at this time: though this able man, by his great industry, made it manifest, in the very infancy of botany, that there is scarce any plant extant in the known world that will not, with proper care, thrive in this kingdom.

When his house at South Lambeth, then called *Tradescant's Ark*, came into Ashmole's possession, he added a noble room to it, and adorned the chimney with his arms, impaling those of Sir William Dugdale, whose daughter was his third wife; where they remain to this day.

It were much to be wished, that the lovers of botany had visited this once famous garden before, or at least in the beginning of the present century. But this seems to have been totally neglected till the year 1749, when Dr Watson and the late Dr Mitchell favoured the Royal Society with the only account now extant of the remains of Tradescant's garden.

When the death of John Tradescant happened is not known; no mention being made thereof in the register-book of Lambeth church.

TRAJECTORY, a term often used, generally for the path of any body, moving either in a void, or in a medium that resists its motion; or even for any curve passing through a given number of points. Thus Newton, Princip. lib. 1. prop. 22. proposes to describe a trajectory that shall pass through five given points.

TRAITOR's ISLAND, one of the Archipelago called NAVIGATOR's *Islands*, in the South Sea (See that article, *Suppl.*). It is low and flat, with only a hill of some height in the middle; and is divided into two parts by a channel, of which the mouth is about 1[illegible] toises wide. It abounds with bannanas, yams, and the finest cocoa-nuts, which Perouse says he ever saw. About twenty canoes approached the French ships without dread, traded with a good deal of honesty, and never refused, like the natives of the archipelago of Navigators, to give their fruit before they were paid for it; nor, like them, did they give a preference to beads over nails and pieces of iron. They spoke, however, the same language, and had the same ferocious look, their dress, their manner of tatowing, and the form of their canoes, were the same; nor could we (says the author) doubt that they were one and the same people: they differed, indeed, in having universally two joints cut off from the little finger of the left hand; whereas, in the islands of Navigators, I only perceived two individuals who had suffered that operation. They were also of much lower stature, and far less gigantic make; a difference proceeding, no doubt, from the soil of these islands, which being less fertile, is consequently less favourable to the expansion of the human frame.

TRAMMELS, in mechanics, an instrument used by artificers for drawing ovals upon boards, &c. One part of it consists of a cross with two grooves at right angles; the other is a beam carrying two pins, which slide in those grooves, and also the describing pencil. All the engines for turning ovals are constructed on the same principles with the trammels: the only difference is, that in the trammels the board is at rest, and the pencil moves upon it; in the turning engine, the tool, which supplies the place of the pencil, is at rest, and the board moves against it. See a demonstration of the chief properties of these instruments by Mr Ludlam, in the *Phil. Transf.* vol lxx. p. 378, &c.

TRANSFORMATION, in geometry, is the changing or reducing of a figure, or of a body, into another of the same area, or the same solidity, but of a different form. As, to transform or reduce a triangle to a square, or a pyramid to a parallelopipedon.

TRANSFORMATION of Equations, in algebra, is the changing equations into others of a different form, but of equal value. This operation is often necessary, to prepare equations for a more easy solution.

TRANSLATION, in literature, is a matter of so much importance, that no other apology can be made for

for the very imperfect manner in which it is treated in the *Encyclopædia*, than a candid declaration that it was impossible to enter at all upon the subject within the narrow limits to which we were then restricted by the proprietors of the work. The fundamental laws of translation, which we gave from Dr Campbell of Aberdeen, we believe indeed to be unexceptionable; but the question is, how are these laws to be obeyed?

In order that a translator may be enabled to give a complete transcript of the ideas of the original work, it is almost needless to observe, that he must possess a perfect knowledge of both languages, *viz*. that of his author, and that into which he is to translate; and that he must have a competent acquaintance with the subject of which his author treats. These propositions we consider as self evident; but if any of our readers shall be of a different opinion, we refer them to an *Essay on the Principles of Translation*, published 1797 by Cadell and Davies, London, where they will find our doctrine very clearly illustrated. It may be proper to add, that such a knowledge of the Greek and Latin languages as merely enables a man to read them with ease and entertainment to himself, is by no means sufficient to qualify him for translating every Greek and Latin book, even though it treats of a subject with which he has a general acquaintance. The religious rites and ceremonies of the Greeks and Romans, as well as the radical words of their language, were derived from the East; and he who is an absolute stranger to oriental literature, will be very liable to mistake occasionally the sense of Greek and Roman authors who treat of religious subjects. We could illustrate the truth of this position by quotations from some of the most admired modern translations of the Greek Scriptures, which we have no hesitation to say fall very short of the authorised version in accuracy as well as in elegance. The divines employed by King James to translate the Old and New Testaments were profoundly skilled in the learning, as well as in the languages, of the East; whilst some of those who have presumed to improve their version seem not to have possessed a critical knowledge of the Greek tongue, to have known still less of the Hebrew, and to have been absolute strangers to the dialect spoken in Judea in the days of our Saviour, as well as to the manners, customs, and peculiar opinions of the Jews sects. Neither metaphysical acuteness, nor the most perfect knowledge of the principles of translation in general, will enable a man who is ignorant of these things to improve the authorised version either of the Gospels or the Epistles; for such a man knows not accurately, and therefore cannot give a complete transcript of the ideas of the original work.

But supposing the translator completely qualified with respect to knowledge, it becomes a question, whether he may, in any case, add to or retrench the ideas of his author? We are strongly inclined to think, that, in no case, it is allowable to take such liberties; but the ingenious and elegant essayist, whose work on the principles of translation we must always quote with respect, is of a different opinion. "To give a general answer (says he) to this question, I would say, that this liberty may be used, but with the greatest caution. It must be further observed, that the superadded idea shall have the most necessary connection with the original thought, and actually increase its force. And, on the other hand, that whenever an idea is cut off by the translator, it must be only such as is an accessory, and not a principle, in the clause or sentence. It must likewise be confessedly redundant, so that its retrenchment shall not impair or weaken the original thought. Under these limitations, a translator may exercise his judgment, and assume to himself, in so far, the character of an original writer."

Of the judicious use, as he thinks it, of this liberty, the author quotes many examples, of which we shall select three, as well calculated to illustrate our own ideas of the subject.

In the first book of the Iliad, Achilles, having resolved, though indignantly, to give up Briseis, desires Petroclus to deliver her to the heralds of Agamemnon;

> Ὡς φατο· Πατροκλος δε φιλῳ επεπειθεθ' εταιρῳ·
> Εκ δ' αγαγε κλισιης Βρισηιδα καλλιπαρηον,
> Δωκε δ' αγειν· τω δ' αυτις ιτην παρα νηας Αχαιων·
> Ἡ δ' αεκουσ' ἁμα τοισι γυνη κιεν· *Iliad*, A. 345.

> Patroclus now th' unwilling beauty brought;
> She in soft sorrows, and in pensive thought,
> Past silent, as the heralds held her hand,
> And oft look'd back, slow moving o'er the strand.
> POPE.

Our author thinks, and we heartily agree with him, that the amplification in the three last lines of this version highly improves the effect of the picture; but we cannot consider this amplification as a new idea superadded. It was the object of Homer to inform his countrymen, that Briseis went with the heralds *unwillingly*. This he does by the words ἡ δ' αεκουσ' ἁμα τοισι γυνη κιεν and it is by no means improbable, that the rhythmical movement of the verse may have presented to the ancient Greeks the image of the lady walking slowly and reluctantly along. This image, we are sure, is not produced by a literal translation of the Greek words into English; and therefore it was Pope's duty, not to add to the ideas of the original, but, by amplification, to present to his own countrymen the picture which Homer, by the superiority of the Greek language and rhythm, had presented to his.

In the ninth book of the Iliad, where Phœnix reminds Achilles of the care he had taken of him while an infant, one circumstance, extremely mean, and even disgusting, is found in the original:

> —— ὁτε δη σ' επ' εμοισιν εγω γουνασσι καθισσας
> Οψου τ' ασαιμι προταμων, και οινον επισχων·
> Πολλακι μοι κατεδευσας επι στηθεσσι χιτωνα,
> Οινου αποβλυζων εν νηπιεη αλεγεινη.

The literal version of these lines is indeed very gross: "When I placed you before my knees, I crammed you with meat, and gave you wine, which you often vomited upon my bosom, and stained my clothes, in your troublesome infancy:" but we cannot agree with our author, that the English reader is obliged to Pope for having altogether sunk this nauseous image. What is, or ought to be, our object in reading Homer? If it be merely to delight our ear with sonorous lines, and please our fancy with grand or splendid images, the translator certainly did right in keeping out of view this disgusting picture of savage life; but when he did so, he cannot be said to have given a complete transcript of his author's ideas. To please ourselves, however, with splendid images, is not our only object when studying the

the works of the ancient poets. Another, and in our opinion a more important object, is to acquire a lively notion of ancient manners; and if so, Pope grossly misleads the mere English reader, when, instead of the beastly image of Homer, he presents him with the following scene, which he may daily meet with in his own family, or in the families of his friends:

> Thy infant breast a like affection show'd,
> Still in my arms, an ever pleasing load;
> Or at my knee, by Phœnix would'st thou stand,
> No food was grateful but from Phœnix hand:
> I pass my watchings o'er thy helpless years,
> The tender labours, the compliant cares.

This is a picture of the domestic manners of Great Britain in the 18th century, and not of Greece in the heroic ages

In the beginning of the eighth book of the Iliad, Homer puts into the mouth of Jove a very strange speech, stuffed with braggart vaunting and ludicrous images. This, as our author observes, is far beneath the dignity of the thunderer; but it is only beneath the dignity of the thunderer as our habits and modes of thinking compel *us* to conceive such a being. The thunderer of the Greeks was a notorious adulterer and sodomite, whose moral character sinks beneath that of the meanest of our bravos; and as he had dethroned his father, and waged for some time a doubtful war with certain *earthly* giants, it does not appear to us that the boasting speech which Homer puts into his mouth is at all unsuitable to his acknowledged attributes. But whether it be or not, was not the translator's concern. Homer, when he composed it, certainly thought it not unworthy of the thunderer; and whatever Pope's opinion might be, he had no right to substitute his own notions of propriety for those of his author. The mythological tales of the poets, and more especially of Homer and Hesiod, constituted, as every one knows, the religious creed of the vulgar Greeks (see POLYTHEISM, n° 33. *Encycl.*); and this circumstance makes it doubly the duty of a translator to give, on such subjects, a fair transcript of his author's ideas, that the mere English reader, for whom he writes, may know what the ancients really thought of the objects of their idolatrous worship. This Pope has not done in the speech under consideration; and has therefore, in our opinion, deviated widely from the first and most important of the three general laws of translation. Johnson has apologized, we think sufficiently, for many of Pope's embellishments of his author; but he has not attempted to make an apology for such embellishments as alter the sense. We cannot indeed conceive a pretence upon which it can ever be allowable in a translator to add to the ideas of his author, to retrench, or to vary them. If he be translating history, and find his author advancing what he *believes* to be false, he may correct him in a note; but he has no right to make one man utter, as his own, the belief or the sentiments of another, when that belief, and those sentiments, are *not* his own. If he be translating a work of science, he may likewise correct the errors of his author in notes, as Dr Clerke corrected those of Rohault; but no man has a right to give to a Rohault the science of a Newton The translator of a poem may certainly employ amplification to place in a striking light the images or the sentiments of the original work; but he must not alter those images or sentiments so as to make that appear grand or elegant in the version, which is mean or disgusting in the original. On every occasion on which he takes such liberties as these, he ceases to be a translator, and becomes a faithless paraphrast.

The second general law of translation, though certainly less important, is perhaps more difficult to be observed than the first. We have stated it in these words: (See TRANSLATION. *Encycl.*) "The style and manner of the original should be preserved in the translation;" but it is obvious, that this cannot be done by him who possesses not sufficient taste and judgment to ascertain with precision to what class the style of the original belongs. "If a translator fail in this discernment, and want this capacity, let him be ever so thoroughly master of the sense of his author, he will present him through a distorting medium, or exhibit him in a garb that is unsuitable to his character." It would obviously be very improper to translate the elegantly simple language of Cæsar into rounded periods like those of *The Rambler*, or the Orations of Cicero into the language of Swift.

The chief characteristic of the historical style of the sacred Scriptures is its simplicity; and that simplicity is, for the most part, well preserved in the authorised version. It is, however, lost in many of the modern versions. Castalio's, for instance, though intitled to the praise of elegant latinity, and though, in general, faithful to the sense of the original, yet exhibits numberless transgressions of the law which is now under consideration. Its sentences are formed in long and intricate periods, in which many separate members are artfully combined: and we observe a constant endeavour at classical phraseology and ornamented diction, instead of the beautiful simplicity of the original.

The version of the Scriptures by Arias Montanus is, in some respects, a contrast to that of Castalio. By adopting the literal mode of translation, Arias undoubtedly intended to give as faithful a picture as he could, both of the sense and of the manner of the original. Not attending to the peculiar idioms of the Hebrew, Greek, and Latin tongues, which, in some respects, are very different from each other, he has, by giving to his Latin the combination and idioms of the two first of these languages, sometimes made the sacred writers talk absurdly. In Latin, as every school boy knows, two negatives make an affirmative, whilst in Greek they add force to the negation. Χωρις εμου ου δυνασθε ποιειν ουδεν signifies, "Without me ye can do nothing," or, "Ye cannot *possibly* do any thing;" but Arias has translated the words *sine me non potestis facere nihil*, *i. e.* "without me ye cannot do nothing," or, "ye *must* do something," which is directly contrary to the meaning of our Lord. It is not therefore by translating literally or verbally that we can hope to preserve the style and manner of the original

To express in florid or elevated language the ideas of an author who writes himself in a simple style, is not to give in the version a just picture of the original; but to attempt, for the sake of verbal accuracy, to introduce into one language the peculiar idioms or construction of another, is still worse, as in this mode of translation the sense, as well as the manner of the original, is lost. The rule obviously is to use, in the version, the words

Translation

words and phraseology which we have reason to believe that the author would himself have used, had he been master of the language into which we are translating his ideas. Thus, if we are to translate into English a piece of elegantly simple Greek or Latin, we must make ourselves completely master of the author's meaning, and, neglecting the Greek or Latin *idioms*, express that meaning in elegantly simple English. We need not add, that when the language of the original is florid or grand, if that style be suited to the subject, the language of the translation should be florid or grand likewise; but care must always be taken that perspicuity be not sacrificed to ambitious ornaments of any kind; for ornaments which obscure the sense are worse than useless.

If these reflections be just, it is obvious that a poem cannot be properly translated into prose. The mere sense may doubtless be thus transferred from one language into another, as has generally been done by Macpherson in his hobbling version of the Iliad, and perhaps more completely by a late translator of Anacreon; but in such a version, the style and manner of the original must necessarily be lost. Of this the following accurate prose translation of Anacreon's ninth ode (on a dove) is a striking instance:

"O lovely Pigeon! whence, whence do you fly? Whence, speeding through the air, do you breathe, and distil so many perfumes? Who is your master? For it concerns me to know. 'Anacreon sent me to a youth, —to Bathyllus, at present the prince, and disposing of all things Venus sold me, receiving a little hymn in return. And I serve Anacreon in such transactions as these: and now I carry his letters, such as you see: and he affirms, that he will immediately make me free. But I will remain a servant with him although he may dismiss me: For wherefore does it behove me to fly, both over mountains, and fields, and to perch on trees, devouring some rustic food? Now indeed I eat bread, snatching it from the hands of Anacreon himself; and he gives to me the wine to drink which he drinks before me; and having drunk, I perhaps may dance, and cover my master with my wings: then going to rest, I sleep upon the lute itself. You have it all;—begone: you have made me more talkative, O mortal! than even a jay *."

* *The Odes of Anacreon, translated into English prose, printed at York, 1796.*

How inferior is the general effect of this piece of prose to that of the well-known poetical versions of Addison and Johnson? and yet the mere *ideas* of the original are perhaps more faithfully transcribed by this anonymous writer than by either of those elegant translators. The emotions indeed excited by the original are not here brought into view.

The third general law of translation is so nearly allied to the second, that we have very few directions to give for the observation of it. He who, in his version, preserves the style and manner of the original, as we have endeavoured to shew that they *ought* to be preserved, will, of course, give to the translation the ease of original composition. The principal difficulty that he has to encounter in this part of his task, will occur in the translating of idiomatical and proverbial phrases. Hardly any two languages are constructed precisely in the same way; and when the structure of the English language is compared with that of the Greek and Latin, a remarkable difference between the ancient and modern tongues is found to pervade the whole. This must occasion very considerable difficulty; but it is a difficulty which will be removed by a due observance of the former law, which directs the translator to make his author speak English in such a style to Englishmen as he spoke his own tongue to his own countrymen, and of course to use the English idiom with English words. But what is to be done with those proverbial phrases of which every language has a large collection, and which allude to local customs and manners?

The ingenious author of the Essay so often quoted, very properly observes, in answer to this question, that the translation is perfect when the translator employs, in his own language, an idiomatic phrase corresponding to that of the original. "It is not (says he) possible perhaps to produce a happier instance of translation by corresponding idioms, than Sterne has given * in the translation of Slawkenbergius's tale. *Nihil me penitet hujus nasi*, quoth Pamphagus; that is, "My nose has been the making of me." *Nec est cur pæniteat*; that is, "How the deuce should such a nose fail?" *Miles peregrini in faciem suspexit!* "The centinel looked into the stranger's face. Never saw such a nose in his life!"

* *Tristra. Shandy.*

"As there is nothing (continues our author) which so much conduces both to the ease and spirit of composition as a happy use of idiomatic phrases, there is nothing which a translator, who has a moderate command of his own language, is so apt to carry to an extreme." Of this he gives many striking examples from Echard's translations of Terence and Plautus, for which we must refer the reader to the Essay itself. He observes, likewise, that in the use of idiomatic phrases, a translator frequently forgets both the country of his original author, and the age in which he wrote; and while he makes a Greek or Roman speak French or English, he unwittingly puts into his mouth allusions to the manners of modern France or England. This, to use a phrase borrowed from painting, may be termed an offence against the *costume*. The proverbial expression βατραχῳ ὕδωρ, in Theocritus, is of similar import with the English proverb, *to carry coals to Newcastle*; and the Scotch, *to drive salt to Dysart*; but it would be a gross impropriety to use either of these expressions in the translation of an ancient classic. Of such improprieties our author points out many instances both in French and English translations of the classics; and he might have increased the number by quotations from Blackwell's Memoirs of the Court of Augustus, where, instead of Roman senators and their wives, we meet with modern gentlemen and ladies, with *secretaries at war*, *paymasters*, *commissary generals*, and *lord high admirals*. It is true the memoirs of the court of Augustus is no translation; but with respect to costume, it is necessarily subject to the laws of translation.

Offences against costume are often committed by the use of improper words as well as of improper phrases. To introduce into dignified and solemn composition words associated with mean and ludicrous subjects, is equally a fault in an original author and in a translator; and it is obviously improper, in the translation of works of very high antiquity, to make use of words which have but lately been admitted into the language of the translator. Faults of this kind are very frequent in Dr Geddes's translation of the Bible, as when the *passover* is called the *skipover*; the tabernacle of the congrega-

tion, the *convention-tent*; and a burnt-offering, a *holocaust*. The first of these expressions presents to the imagination an image profanely ludicrous: the second, brings into our view the French Convention, which, we suspect, occupied no small portion of the Doctor's thoughts, when they should have been wholly employed on the sacred text; and the word *holocaust*, which must be unintelligible to the mere English reader, is, in the mind of every man of letters, closely associated with the abominable rites performed at the sacrifices of the ancient heathens. But it is needless to point out faults of this kind in a work which is open to more serious objections, and which, we trust, shall never be generally read. We are sorry that truth compels us to say, that the novel expressions introduced by Dr Campbell into his version of the gospels—such as *confluence* for multitude, and *reign* for kingdom—are, to say the best of them, no improvements of the authorised version. We will not rank them with Dr Geddes's innovations, because we will not class the great author of the *Dissertation on Miracles* with a paradoxical Christian of no communion; but we do not think that Dr Campbell's laurels were freshened on his brow by the translation of the Gospels.

We shall conclude this article with the following reflections, taken from the Essay which has been so often quoted:

"If the order in which we have classed the three general laws of translation be their just and natural arrangement, which, we presume, will hardly be denied, it follows, that, in every case where it is necessary to make a sacrifice of one of these laws to another, a due regard ought to be paid to their rank and comparative importance. When the genius of the original language differs much from that of the translation, it is often necessary to depart from the author's manner in order to convey a faithful picture of his sense; but it would be highly preposterous to depart, in any case, from the sense, for the sake of imitating the manner. Equally improper would it be, to sacrifice either the sense or manner of the original, if these can be preserved consistently with purity of expression, to a fancied ease or superior gracefulness of composition; and it is certain that the sense may always be preserved, though to purity of expression the manner of the original must sometimes be sacrificed."

TRAPEZOID, sometimes denotes a trapezium that has two of its sides parallel to each other; and sometimes an irregular solid figure, having four sides not parallel to each other.

TRAVERSE, in gunnery, is the turning a piece of ordnance about, as upon a centre, to make it point in any particular direction.

Traverse, in fortification, denotes a trench with a little parapet, sometimes two, one on each side, to serve as a cover from the enemy that might come in flank.

Traverse, in a wet foss, is a sort of gallery, made by throwing saucissons, joists, fascines, stones, earth, &c. into the foss, opposite the place where the miner is to be put, in order to fill up the ditch, and make a passage over it.

Traverse also denotes a wall of earth, or stone, raised across a work, to stop the shot from rolling along it.

Traverse also sometimes signifies any retrenchment, or line fortified with fascines, barrels, or bags of earth, or gabions.

TRAVESTY, or burlesque translation, is a species of writing which, as it partakes, in a great degree of original composition, is not to be measured by the laws of serious translation. It conveys neither a just picture of the sentiments, nor a faithful representation of the style and manner of the original; but pleases itself in exhibiting a ludicrous caricatura of both. It displays an overcharged and grotesque resemblance, and excites our risible emotions by the incongruous association of dignity and meanness, wisdom and absurdity. This association forms equally the basis of travesty and of ludicrous parody, from which it is no otherwise distinguished than by its assuming a different language from the original. In order that the mimickry may be understood, it is necessary that the writer choose, for the exercise of his talents, a work that is well known, and of great reputation. Whether that reputation is deserved or unjust, the work may be equally the subject of burlesque imitation. If it has been the subject of general, but undeserved praise, a parody or a travesty is then a fair satire on the false taste of the original author and his admirers, and we are pleased to see both become the objects of a just castigation. The *Rehearsal*, *Tom Thumb*, and *Chrononhotonthologos*, which exhibit ludicrous parodies of passages from the favourite dramatic writers of the times, convey a great deal of just and useful criticism. If the original is a work of real excellence, the travesty or parody detracts nothing from its merit, nor robs the author of the smallest portion of his just praise. We laugh at the association of dignity and meanness; but the former remains the exclusive property of the original, the latter belongs solely to the copy. We give due praise to the mimical powers of the imitator, and are delighted to see how ingeniously he can elicit subjects of mirth and ridicule from what is grave, dignified, pathetic, or sublime.

But this species of composition pleases only in a short specimen. We cannot bear a lengthened work in travesty. The incongruous association of dignity and meanness excites risibility chiefly from its being unexpected. Cotton's and Scarron's Virgil entertain but for a few pages: the composition soon becomes tedious, and at length disgusting. We laugh at a short exhibition of buffoonery; but we cannot endure a man who, with good talents, is constantly playing the fool.

TREACLE (see *Encycl.*) or Melasses, is a substance very wholesome, but of a taste disagreeably sweet. Methods have accordingly been proposed for purifying it, so as that it may, on many occasions, supply the place of refined sugar, which has long been at a price which a great number of poor persons cannot afford to pay for what must now be considered as a necessary of life. The following is the process for purifying treacle, given by the M. Cadet (Devaux) in the *Feuille du Cultivateur*, founded upon experiments made by Mr Lowitz of Petersburgh:

Take of treacle 24 lbs. of water 24 lbs. of charcoal, thoroughly burnt, 6 lbs. Bruise the charcoal grossly, mix the three substances in a caldron, and let the mixture boil gently upon a clear wood-fire. After it has boiled for half an hour, pour the liquor through a straining-bag, and then replace it upon the fire, that the superfluous water may be evaporated, and that the treacle may be brought to its original consistence. There is little or no loss by this operation, as 24 lbs. of treacle give nearly the same quantity of syrup.

This process has been repeated in the large way, and has succeeded: the treacle is sensibly ameliorated, so

Trebiſond. ‖ Triangle.

that it may be uſed for many diſhes; nevertheleſs, those with milk, and the ſine or aromatic *liqueurs*, are not near ſo good as with ſugar.

TREBISOND, a large, populous, and ſtrong town of Turkey in Aſia, in the province of Jenich, with a Greek archbiſhop's ſee, a harbour, and a caſtle. It is ſeated at the foot of a very ſteep hill. The walls are ſquare and high, with battlements; and are built with the ruins of ancient ſtructures, on which are inſcriptions not legible. The town is not populous; for there are more woods and gardens in it than houſes, and theſe but one ſtory high. The caſtle is ſeated on a flat rock, with ditches cut therein. The harbour is at the eaſt end of the town, and the mole built by the Geneoſe is almoſt deſtroyed. It ſtands on the Black Sea, 104 miles north-weſt of Erzerum, and 440 eaſt of Conſtantinople. E. Long. 4[illegible] 25. N. lat. 40° 45.

TREE. Under this title (*Encycl.*) we gave an account of the method recommended by Meſſrs Forſyth and Hitt for curing injuries and defects in trees. The actual cautery is employed in Cevennes, and in the department de l'Allier, in France, for ſtopping the progreſs of rottenneſs in large trees. When they perceive that this very common and deſtructive diſeaſe begins to make ſome progreſs in the cheſnut-tree, by excavating its trunk, they collect heath, and other combuſtible vegetables, and burn them in the very cavity, till the ſurface is completely converted into a coal. It ſeldom happens that the tree periſhes by the effect of this operation, and it is always found that this remedy ſuſpends the progreſs of the decay. It is practiſed in the ſame manner, and with ſimilar ſucceſs, on the white oak. When we compare the effects of the actual cautery on the animal ſyſtem, in ſimilar diſeaſes, a new reſemblance is ſeen between the diſeaſes which affect the organic beings of both kingdoms, as well as between the remedies by which they may be oppoſed.—*Nicholſon's Journal.*

TRIANGLE, Arithmetical, a kind of numeral triangle, or triangle of numbers, being a table of certain numbers diſpoſed in form of a triangle. It was ſo called by Paſcal; but he was not the inventor of this table, as ſome writers have imagined, its properties having been treated of by other authors ſome centuries before him, as is ſhewn in Dr Hutton's Mathematical Tracts, vol. i. p. 69. &c.

The form of the triangle is as follows:

1					
1	1				
1	2	1			
1	3	3	1		
1	4	6	4	1	
1	5	10	10	5	1
1	6	15	20	&c.	
1	7	21	&c.		
1	8	&c.			
1	9				
1					

And it is conſtructed by adding always the laſt two numbers of the next two preceding columns together, to give the next ſucceeding column of numbers.

The firſt vertical column conſiſts of units; the ſecond, a ſeries of the natural numbers 1, 2, 3, 4, 5, &c.; the third, a ſeries of triangular numbers 1, 3, 6, 1[illegible], &c.; the fourth, a ſeries of pyramidal numbers, &c. The oblique diagonal rows, deſcending from left to right, are alſo the ſame as the vertical columns. And the numbers taken on the horizontal lines are the coefficients of the different powers of a binomial. Many other properties and uſes of theſe numbers have been delivered by various authors, as may be ſeen in the Introduction to Hutton's Mathematical Tables, pages 7, 8, 75, 76, 77, 89, ſecond edition.

Triangular ‖ Trinitarians.

TRIANGULAR Compasses, are ſuch as have three legs or feet, by which any triangle, or three points, may be taken off at once. Theſe are very uſeful in the conſtruction of maps, globes, &c.

Triangular Numbers, are a kind of polygonal numbers; being the ſums of arithmetical progreſſions, which have 1 for the common difference of their terms.

Thus, from theſe arithmeticals 1 2 3 4 5 6,
are formed the triangular numbers 1 3 6 10 15 21,
or the third column of the arithmetical triangle abovementioned.

The ſum of any number n of the terms of the triangular numbers, 1, 3, 6, 10, &c. is =

$$\frac{n^3}{6}+\frac{n^2}{2}+\frac{n}{3}, \text{ or } \frac{n}{1}\times\frac{n+1}{2}\times\frac{n+2}{3}$$

which is alſo equal to the number of ſhot in a triangular pile of balls, the number of rows, or the number in each ſide of the baſe, being n.

The ſum of the reciprocals of the triangular ſeries, infinitely continued, is equal to 2; viz.

$$1+\tfrac{1}{3}+\tfrac{1}{6}+\tfrac{1}{10}+\tfrac{1}{15}, \&c. = 2.$$

For the rationale and management of theſe numbers, ſee *Malcolm's Arith.* book 5. ch. 2.; and *Simpſon's Algeb.* ſec. 15.

TRIESTE, a ſmall, but ſtrong and ancient ſeaport of Italy, in Iſtria, on the gulph of Venice, with a biſhop's ſee. It is beautifully ſituated on the ſide of a hill, about which the vineyards form a ſemicircle. The ſtreets are narrow; but there is a large ſquare, where they keep the annual fair. The harbour is ſpacious, but not good; becauſe it is open to the W. and S. W. winds. The inhabitants have a good trade in ſalt, oil, almonds, iron, &c. brought from Laubach; and they make good wines. The cathedral, and the late Jeſuits church, are the two beſt buildings. It belongs to the Houſe of Auſtria, and is eight miles north of Capo d'Iſtria, and 8[illegible] north-eaſt of Venice. E. Long. 14. 4. N. Lat. 45. 56.

TRINITARIANS (Order of), was inſtituted at Rome in the year 1198, under the pontificate of Innocent III. the founders whereof were John de Matha and Felix de Valois. His Holineſs gave them permiſſion to eſtabliſh this order for the deliverance of captives, who groaned under the tyranny of the infidels: he gave them as a habit a white gown, ornamented with a red and blue croſs. After the death of the two founders, Pope Honorious III. continued the order; and their rule was approved by his ſucceſſor Clement IV. in 1267. At firſt they were not permitted to eat fleſh; and when they travelled, were to ride only upon aſſes. But their rule was corrected and mitigated by the biſhop of Paris, and the abbots of St Victor and St Genevieve, who allowed them to eat any kind of food, and to uſe horſes. This order poſſeſſed, at one time, about 250 convents in 13 different provinces: ſix of which were in France; namely, France, Normandy, Picardy, Champaine, Languedoc, and Provence; three in Spain, viz. New Caſtile, Old Caſtile, and Arragon; one in Italy, and one in Portugal. There was formerly the province of England, where this order had 43 houſes; that of Scotland, where it had nine; and that

that of Ireland, where it had 52; beſides a great number of monaſteries in Saxony, Hungary, Bohemia, and other countries. The convent of Cerfroy in France was head of the order. It is impoſſible for us to ſay what is now the ſtate of the order, which can have no viſible exiſtence in France, and is probably ſuppreſſed even in Italy.

TRIONES, in aſtronomy, a ſort of conſtellation, or aſſemblage of ſeven ſtars in the Urſa Major, popularly called *Charles's Wain*.—From the *ſeptem triones* the north pole takes the denomination *ſeptentrio*.

TRIPOLI OF SYRIA is, according to Mr Browne, by no means ſo populous a place as we were led to repreſent it in the *Encyclopædia*. It is indeed, he ſays, a city of ſome extent, ſituated about a mile and a half from the ſea; but inſtead of ſixty, he eſtimates its population at about ſixteen thouſand. The air is rendered unwholeſome by much ſtagnant water. The town is placed on a ſlight elevation, the length conſiderably exceeding the breadth. On the higheſt ground, to the ſouth, is the caſtle, formerly poſſeſſed by the earls of Tripoli; it is large and ſtrong. Hence is viſible a part of mount Libanus, the ſummit of which is covered with ſnow. The gardens in the vicinity are rich in mulberry and other fruit trees. The city is well built, and moſt of the ſtreets are paved.

Here is found a number of Mohammedan merchants, ſome of the richeſt and moſt reſpectable in the empire. Silk is the chief article of commerce.

The *miri*, or fixed public revenue paid by Tripoli to Conſtantinople, is only about L. 1000 Sterling, 20 purſes, a-year. Syria at preſent contains only four Paſhaliks, Damaſcus, Aleppo, Acrê, and Tripoli; the laſt of which is the ſmalleſt in territory and power. Our author obſerved no antiquities at Tripoli; but the country round it is noted for producing the beſt tobacco in Syria.

TRISECTION, the dividing a thing into three equal parts. The term is chiefly uſed in geometry, for the diviſion of an angle into three equal parts. The *triſection of an angle* geometrically, is one of thoſe great problems, whoſe ſolution has been ſo much ſought for by mathematicians for 2000 years paſt; being, in this reſpect, on a footing with the famous quadrature of the circle, and the duplicature of the cube.

TRISTAN D'ACUNHA, the largeſt of three iſlands which were viſited by Lord Macartney and his ſuite on the 31ſt of December 1792. The other two are diſtinguiſhed by the names of *Inacceſſible* and *Nightingale* iſlands. "Inacceſſible (as Sir Eraſmus Gower obſerved) ſeems to deſerve that name, being a high, bluff, as well as apparently barren plain, about nine miles in circumference, and has a very forbidding appearance. There is a high rock detached from it at the ſouth end. Its latitude is 37° 19′ ſouth; its longitude 11° 50′ weſt from Greenwich. This rude looking ſpot may be ſeen at 12 or 14 leagues diſtance. Nightingale iſland is irregular in its form, with a hollow in the middle, and is about ſeven or eight miles in circumference, with ſmall rocky iſles at its ſouthern extremity. It is deſcribed as having anchorage on the north-eaſt ſide. Its latitude is 37° 29′ ſouth; and longitude 11° 48′ weſt from Greenwich. It may be ſeen at ſeven or eight leagues diſtance. The largeſt of theſe three iſlands, which comparatively may be called the great iſle of *Triſtan d'Acunha*, is very high, and may be ſeen at 25 leagues diſtance. It ſeems not to exceed in circumference 15 miles. A part of the iſland towards the north riſes perpendicularly from the ſea to a height apparently of a thouſand feet or more. A level then commences, forming what among ſeamen is termed *table land*, and extending towards the centre of the iſland; from whence a conical mountain riſes, not unlike in appearance to the Peak of Teneriffe, as ſeen from the bay of Santa Cruz. Boats were ſent to ſound and to examine the ſhore for a convenient place to land and water. In conſequence of their report, the Lion (a ſhip of 64 guns) ſtood in, and came to anchor in the evening on the north ſides in 30 fathoms water, one mile from the ſhore; the bottom black ſand with ſlime; a ſmall rock, off the weſt point, bearing ſouth weſt by ſouth juſt open with the weſtern extremity of the iſland; a caſcade, or fall of water, emptying itſelf upon the beach, ſouth by eaſt. All the ſhore, from the ſouthern point to the eaſtern extremity, appears to be clear of danger, and ſteep, except the weſt point, where there are breakers about two cables length, or near 500 yards from the ſhore. The ſhip, when anchored, was overſhadowed by the dark maſs of that portion of the iſland whoſe ſides ſeemed to riſe, like a moſs-grown wall, immediately from the ocean. On the right the elevation was leſs rapid, and between the riſing part and the ſea was left a flat, of ſome extent, covered with ſedge graſs, interſperſed with ſmall ſhrubs, which, being perfectly green, looked from the ſhip like a pleaſant meadow, watered by a ſtream that fell, afterwards, from its banks upon the beach. The officers, who went aſhore, reported, that the caſks might be filled with freſh water by means of a long hoſe, without moving them from the boats. The landing place thereabouts was alſo deſcribed as being ſafe, and ſuperior to any other that had been examined. From the plain, the land roſe gradually towards the central mountain, in ridges covered with trees of a moderate ſize and height. The coaſt abounded with ſea lions and ſeals, penguins and albatroſſes. One of the latter was brought on board, his wings meaſuring ten feet from tip to tip; but others are ſaid to have been found much larger. The coaſt was covered with a broad ſea weed, ſeveral fathoms long, and deſervedly by naturaliſts termed *gigantic fucus*. Some good fiſh was caught with the hook and line.

"The accident of a ſudden guſt, by which the anchor was in a few hours driven from its hold, and the ſhip forced out to ſea, prevented the iſland from being explored, as was intended. It is probable that had the Lion anchored in 20, inſtead of 30 fathoms water, the anchor would have held firmly. Some advantage was obtained, however, from coming to this place. The juſt poſition of thoſe iſlands, in reſpect to their longitude, was aſcertained, by the mean of ſeveral timepieces, to be about two degrees to the eaſtward of the place where they are laid down in charts, taken from obſervations made at a period when the inſtruments for this purpoſe were leſs accurate than at preſent. The ſpot where the Lion anchored was determined, by good meridional obſervations, and by accurate time-pieces, to be 37° 6′ ſouth latitude, and 11° 43′ weſt longitude from Greenwich. The compaſs had ſeven degrees of variation weſtward from the pole. Fahrenheit's thermometer ſtood at 67 degrees. It was uſeful alſo to have aſcertained, that a ſafe anchorage and plenty of good water, were to be found here. Theſe iſlands are certainly worthy of a more particular inquiry; for they are not 50 leagues from the general track of veſ-

sels bound to China, and to the coast of Coromandel, by the outer passage. In war time, an excellent rendezvous might be settled there, for ships that wanted no other supply but that of water. When circumstances require particular dispatch, it is practicable to come from England to Tristan d'Acunha without stopping in the way, and afterwards to the end of the voyage to India or China."

These islands are separated by a space of about fifteen hundred miles from any land to the westward or northward of them. They are situated in that part of the southern hemisphere, in the neighbourhood of which a continent, to balance the quantity of land in the northern hemisphere, was once expected to be found, but where it has been since discovered that there is none. Of what extent, however, the bases of these islands are under the surface of the sea, cannot be ascertained; or whether they may, or may not, be sufficient to make up for the defect of land appearing above water. Navigators report, that to the eastward of them are other small islands, differing not much in latitude, such as Gough and Alvarez islands, and the Marsouines; as well as extensive shoals, lying due south of the most southerly point of Africa, and extending easterly several degrees. That all these together form a chain, some of subaqueous, and some of superaqueous mountains, but all connected by their roots, is perhaps a conjecture less improbable, than that they should separately arise, like tall columns, from the vast abyss.

A settlement in Tristan d'Acunha is known to have been twice in the contemplation of adventurers, but not as yet to have been carried into execution. One had the project of rendering it a mart for the change of the light manufactures of Hindostan, suited to hot climes, for the silver of the Spanish settlements in South America; in the route between which places it is conveniently situated. The other plan meant is only as a suitable spot for drying and preparing the furs of sea lions and seals, and for extracting the spermaceti of the white or long nosed whale, and the whale-bone and oil of the black species. Whales of every kind were seen sporting about Tristan d'Acunha, particularly near the setting of the sun; and the sword fish likewise made its appearance occasionally.—*Sir George Staunton's Account of the Embassy to China.*

TRITON, in zoology, a genus belonging to the order of vermes mollusca. The body is oblong; the tongue is spiral; it has twelve tentacula, six on each side, the hindmost ones having claws like a crab. There is but one species, found in holes of rocks about the shore.

TROTTER (Mrs Catharine), was the daughter of Captain David Trotter, a Scotch gentleman. He was a commander in the royal navy in the reign of Charles II. and at his death left two daughters, the youngest of whom, Catharine, our celebrated author, was born in London, August 1679. She gave early marks of her genius; and learned to write, and also made herself mistress of the French language, by her own application and diligence, without any instructor; but she had some assistance in the study of the Latin grammar and logic, of which latter she drew up an abstract for her own use. The most serious and important subjects, and especially religion, soon engaged her attention.—But notwithstanding her education, her intimacy with several families of distinction of the Romish persuasion, exposed her, while very young, to impressions in favour of that church; which not being removed by her conferences with some eminent and learned members of the church of England, she embraced the Romish communion, in which she continued till the year 1707. In 1695, she produced a tragedy called *Agnes de Castro*, which was acted at the theatre-royal when she was only in her 17th year. The reputation of this performance, and the verses which she addressed to Mr Congreve upon his Mourning Bride, in 1697, were probably the foundation of her acquaintance with that celebrated writer. Her second tragedy, *Fatal Friendship*, was acted in 1698, at the new theatre in Lincoln's-Inn-Fields. This tragedy met with great applause, and is still thought the most perfect of her dramatic performances. Her dramatic talents not being confined to tragedy, she brought upon the stage, in 1701, a comedy called *Love at a loss*, or *Most votes carry it*. In the same year she gave the public her third tragedy, entitled the *Unhappy Penitent*, acted at the theatre royal in Drury-lane. But poetry and dramatic writing did not so far engross the thoughts of our author but that she sometimes turned them to subjects of a very different nature; and distinguished herself in an extraordinary manner in defence of Mr Locke's writings; a female metaphysician being a remarkable phenomenon in the republic of letters.

She returned to the exercise of her dramatic genius in 1703, and fixed upon the revolution of Sweden, under Gustavus Erickson, for the subject of a tragedy. This tragedy was acted, in 1706, at the Queen's theatre in the Hay-Market. In 1707, her doubts concerning the Romish religion, which she had so many years professed, having led her to a thorough examination of the grounds of it, by consulting the best books on both sides of the question, and advising with men of the best judgment, the result was a conviction of the falseness of the pretensions of that church, and a return to that of England, to which she adhered during the remainder of her life. In 1708, she was married to the Rev. Mr Cockburn, then curate of St Dunstan's in Fleet-street, but he afterwards obtained the living of Long-Horsely, near Morpeth in Northumberland. He was a man of considerable abilities; and, among several other things, wrote an account of the Mosaic Deluge, which was much approved by the learned.

Mrs Cockburn's remarks upon some writers in the controversy concerning the foundation of moral duty and moral obligation, were introduced to the world, in August 1743, in the Literary Journal, intitled *The History of the Works of the Learned.* The strength, clearness, and vivacity shewn in her remarks upon the most abstract and perplexed questions, immediately raised the curiosity of all good judges about the concealed writer; and their admiration was greatly increased when her sex and advanced age were known. Dr Rutherforth's Essay on the Nature and Obligations of Virtue, published in May 1744, soon engaged her thoughts; and notwithstanding the asthmatic disorder, which had seized her many years before, and now left her small intervals of ease, she applied herself to the confutation of that elaborate discourse, and finished it with a spirit, elegance, and perspicuity equal, if not superior, to all her former writings.

The loss of her husband in 1748, in the 71st year of his age, was a severe shock to her; and she did not long survive him, dying on the 11th of May 1749, in her

Trumpet Marine.

71st year, after having long supported a painful disorder with a resignation to the Divine will, which had been the governing principle of her whole life, and her support under the various trials of it.

Her works are collected into two large volumes 8vo, by Dr Birch; who has prefixed to them an account of her life and writings.

TRUMPET Marine, or Marigny. This is a stringed instrument, invented in the 16th century by an Italian artist Marino or Marigni, and called a *trumpet*, because it takes only the notes of the trumpet, with all its omissions and imperfections, and can therefore execute only such melodies as are fitted for that instrument. It is a very curious instrument, though of small musical powers, because its mode of performance is totally unlike that of other stringed instruments; and it deserves our very particular attention, because it lays open the mechanism of musical sounds more than any thing we are acquainted with; and we shall therefore make use of it in order to communicate to our readers a philosophical theory of music, which we have already treated in detail as a liberal or scientific art.

Plate XLV.

The trumpet marine is commonly made in the form of a long triangular pyramid, ABCD, fig. A. on which a single string EFG is strained over a bridge F by means of the finger pin L. At the narrow end are several frets 1, 2, 3, 4, 5, &c. between E and K, which divide the length EF into aliquot parts. Thus E 1 is $\frac{1}{12}$ of EF, E 2 is $\frac{1}{11}$, and so on. The bow is drawn lightly across the cord at H, and the string is stopped by pressing it with the finger immediately above the frets, but not so hard as to make it touch the fret. When the open string is sounded, it gives the fundamental note. If it be stopped, in the way now described, at $\frac{1}{3}$d of its length from E, it yields the 12th of the fundamental; if stopped at $\frac{1}{4}$th, it gives the double octave; if at $\frac{1}{5}$th, it gives the 17th major, &c. In short, it always gives the note corresponding to the length of the part between the fret and the nut E. The sounds resemble those of a pipe, and are indeed the same with those known by the name *harmonics*, and now executed by every performer on instruments of the viol or violin species. But in order to increase the noise, the bridge F is constructed in a very particular manner. It does not rest on the sound-board of the instrument through its whole breadth, but only at the corner *a*, where it is firmly fixed. The other extremity is detached about $\frac{1}{100}$ of an inch from the sound board; and thus the bridge, being made to tremble by the strong vibration of the thick cord, rattles on the sound-board, or on a bit of ivory glued to it. The usual way in which this motion is procured, is to have another string passing under the middle of the bridge in such a manner that, by straining it tight, we raise the corner *b* from the sound-board to the proper height. This contrivance increases prodigiously the noise of the instrument, and gives it somewhat of the smart sound of the trumpet, tho' very harsh and coarse. But it merits the attention of every person who wishes to know any thing of the philosophy of musical sounds, and we shall therefore say as much on the subject as will conduce to this effect.

Galileo, as we have observed in the article Temperament, *Suppl.* was the first who discovered the real connection between mathematics and music, by demonstrating that the times of the vibrations of elastic cords of the same matter and size, and stretched by equal weights, are proportional to the lengths of the strings. He inferred from this that the musical pitch of the sound produced by a stretched cord depended solely on the frequency of the vibrations. Moreover, not being able to discover any other circumstance in which those sounds physically resembled each other, and reflecting that all sounds are immediately produced by agitations of air acting on the ear, he concluded that each vibration of the cord produced a sonorous pulse in the air, and therefore that the pitch of *any* sound whatever depended on the frequency of the aerial pulses. In this way alone the sound of a string, of a bell, of an organ pipe, and the bellow of a bull, may have the same pitch. He could not, however, demonstrate this in any case but the one above mentioned. But he was encouraged to hope that mathematicians would be able to demonstrate it in all cases, by his having observed that the same proportions obtained in organ pipes as in strings stretched by equal weights. But it required a great progress in mechanical philosophy, from the state in which Galileo found it, before men could speculate and reason concerning the pulses of air, and discover any analogy between them and the vibrations of a string. This analogy, however, was discovered, and its demonstration completed, as we shall see by and by. In the mean time, Galileo's demonstration of the vibrations of elastic cords became the foundation of all musical philosophy. It must be thoroughly understood before we can explain the performance of the trumpet marine.

The demonstration of Galileo is remarkable for that beautiful simplicity and perspicuity which distinguish all the writings of that great mechanician, and it is the elementary proposition in all mechanical treatises of music. Few of them indeed contain any thing more; but it is extremely imperfect, and is just only on the supposition that all the matter of the string is collected at its middle point, and that the rest of it has elasticity without *inertia*. This did not suit the accurate knowledge of the last century, after Huyghens and Newton had given the world a taste of what might be done by prosecuting the Galilean mechanics. When a musical cord has its middle point drawn aside, and it is strained into the shape of two strait lines, if it be let go will be observed not to vibrate in this form. It may easily be seen in the extremity of its excursions, where it rests, before it return by its elasticity. The reason is this (see fig. B.) When the middle point C of the cord is drawn aside, and the cord has the form of two straight lines AC, CB, this point C, being pulled in the directions CA, CB, at once, is really accelerated in the direction CD, which bisects the angle ACB; and if it were then detached from the rest of the material cord, it would move in that direction. But any other point *f* between C and B has no accelerating force whatever acting on it. It is equally pulled in the directions *f*C and *f*B. The particle C therefore is obliged to drag along with it the inert matter of the rest of the cord; and when it has come to any intermediate situation *c*, the cord cannot have the form of two straight lines A *c*, *c* B, with the particle *f* situated in *'f*. This particle will be left somewhat behind, as in *r*, and the cord will have a curved form A *c r* B; and in this form it will vibrate, going to the other side, and assuming, not the rectilineal form ADB, but the curved form A*δ*B.

Trumpet Marine.

Ac'B. That every particle of the curve A$e c'f$B is now accelerated toward the axis AB is evident, because every part is curved, and the whole is strained toward A and B, which tends to straighten every part of it. But in order that the whole may arrive at the axis in one moment, and constitute a straight line AB, it is evidently necessary that the accelerating force on every particle be as the distance of the particle from that point of the axis at which it arrives. It is well known to the mathematician that the accelerating force by which any particle is urged towards a rectilineal position, with respect to the adjoining particles, is proportional to the curvature. Our readers who are not familiar with such discussions, may see the truth of this fundamental proposition by considering the whole of AcB as only a particle or minute portion of a curve, magnified by a microscope. The force which strains the curve may be represented by cA or AE. Now it is well known (and is the foundation of Galileo's demonstration) that the straining force is to the force with which c is accelerated in the direction cE as Ac to cD, or as AE to cD, or as AE to twice cE. Now cE is the measure of the curvature of AcB, being its deflection from a right line. Therefore when the straining force is the same all over the curve, the accelerating force, by which any portion of it tends to become straight, is proportional to the curvature of that portion. And if r be the radius of a circle passing through A, c, and B, and coinciding with this element of a curve, it is plain that $cD : cA = cA : r$, or that the radius of curvature is to the element cA as the extending force to the accelerating force; and $cD = \frac{cA^2}{r}$; and is inversely as r, or directly as the curvature.

Hence we see the nature of that curve which a musical chord must have, in order that all its parts may arrive at the axis at once. The curvature at c must be to the curvature at f as Ec to gf. But this may not be enough. It is farther necessary that when c has got half way to E, the curvature in the different points of the new curve into which the cord has now arranged itself, be also, in every point, proportional to the distance from the axis. Now this *will* be the case if the extreme curve has been such. For, taking the cord in any other successive shape, the distance which each point has gone in the same moment must be proportional to the force which impelled it; therefore the remaining distances of all the points from the axis will have the same proportions as before. And the geometrical and evident consequence of this is, that the curvatures will also be in the same proportion.

Therefore a cord that is once arranged in this form will always preserve it, and will vibrate like a cycloidal pendulum, performing its oscillations in equal times, whether they be wide or narrow. Therefore since this perfect isochronism of vibrations is all that is wanted for preserving the same musical pitch or tone, this cord will always have the same note.

This proposition was the discovery of Dr Brooke Taylor, one of the ornaments of our country *, and is published in his celebrated work *Methodus Incrementorum*. The investigation, however, and the demonstration in that work, are so obscure and so tedious that few had patience to peruse them. It was more elegantly treated afterwards by the Bernoullis and others. The curve got the name of the *Taylorean curve;* and is considered by many eminent mathematicians as a trochoid, *viz.* the curve described by a point in the nave or spoke of a wheel while the wheel rolls along a straight line. But this is a mistake, although it is allied to the trochoid in the same manner that the figure of sines is allied to the cycloid. Its physical property intitles it to the name of the HARMONICAL CURVE. As this curve is not only the foundation of all our knowledge of the vibration of elastic cords, but also furnishes an equation which will lead the mathematician through the whole labyrinth of aereal undulations, and be of use on many other occasions; and as the first mathematicians have, through inattention, or through enmity to Dr Taylor, affected to consider it as the trochoid already well known to themselves—we shall give a short account of its construction and chief properties, simplified from the elegant description given by Dr Smith in his Harmonics.

* See his life, *Encycl.*

Let SDTV, QERP (fig. C.), be circles described round the centre C. Draw the diameters QCR, ECP, cutting each other at right angles. From any point G in the exterior circle draw the radius GC, cutting the interior circle in F, draw KHFI parallel to QCR, and make HI, HK, each equal to the arch EG. Let this be done for every point of the quadrantal arch EGR. The points I, K, are in the harmonic curve; that is, the curve AKDIB passing through the points K and I, determined by this construction, has its curvature in every point K proportional to the distance KN from the base AB.

To demonstrate this, draw FL perpendicular to the axis, and join EL. Take another point g in the outer circle indefinitely near to G. Draw gc, cutting the inner circle in f, and fh and fl perpendicular to DC, CP, and join El. Then suppose two lines Km', Km' perpendicular to the curve in K and k. They must meet in m, the centre of the equicurve circle. Draw KNn' perpendicular to the base, and $m'n'$ parallel to it, and join kn. Lastly, draw Xix perpendicular to EL.

It is plain that kO, the difference of HK and hk, is equal to Gg, the difference of GE and gE, and that KO is equal to Fr, and Ll to rf. Also, because ELX is a right angle, $EX = \frac{EL^2}{EC}$.

We have $Fr : Ff = CL : CF, = CL : CD.$

$Ff : Gg = CD : CE.$

Therefore $Fr : Gg$, or $KO : Ok = CL : CE$.

The triangles ECL and kOK are therefore similar, as are also kOK and Knm, and consequently ECL and Knm; and because EC is parallel to Kn, EL is parallel to Km. For the same reason km is parallel to El, and the triangles Elx and mKk are similar, and

$Lx : Kk = LE : Km,$

and $Lx : Kk = EC : Kn$. But farther,

$Lx : Ll = CE : CL$

$Ll : Ff = KN : CD$, being $= FL : FC$

$Ff : Gg = CD : CE$, being $= Ff : kO$

$Gg : Kk = CE : CL$; being $= KO : Kk$.

Therefore $Lx : Kk = KN \times CE : EL^2, = KN : EX$.

Therefore $KN : EX = LE : Km$, and $Km = \frac{EX \cdot LE}{KN}$

and $KN : EX = CE : Kn$, and $Kn = \frac{EX \cdot CE}{KN}$

In

In the very narrow vibrations of musical cords, CD is exceedingly small in comparison with CE, so that EX·EL, or EX·CE, may, without sensible error, be taken for CE^2, and then we obtain Km or Kn (which hardly differ) $= \frac{CE^2}{KN}$, and therefore the curvature is proportional to KN. The small deviation from this ratio would seem to shew that this construction does not give the harmonic curve with accuracy. But it is not so. For it will be found that although the curvature is not as KN, it is still proportional to the space which any particle K must really describe in order to arrive at the axis. These paths are lines whose curvatures diminish as they approach to DC.

We see, *1st*, that the base ACB of the curve is equal to the semicircular arch QER.

2d, Also that the tangent KZ in any point K is perpendicular to EL.

3d. We learn that the curvature at A and B is nothing, for in these two points KN is nothing.

4th, The radius of curvature at D is precisely $= \frac{CE^2}{CD}$.

Therefore, as the string approaches the axis, and CD diminishes, the curvature diminishes in the same proportion. The vibrations therefore are performed like those of a pendulum in a cycloid, and are isochronous, whether wide or narrow, and therefore the musical pitch is constant.

This is not strictly true, because in the wide vibrations the extension or extending force is somewhat greater. Hence it is that a string when violently twanged sounds a little sharper at the beginning. Dr Long made a harpsichord whose strings were stretched by weights, by which this imperfection was removed.

It is proper to exhibit the curvature at D in terms of the length AB, and of the greatest excursion c D. Therefore let c be the circumference of a circle whose diameter is 1. Let AB the length of the cord be $=$ L, and let CD the $\frac{1}{2}$ breadth of the vibration be B.

We had a little ago $Dm = \frac{CE^2}{CD}$, but $c : 1 = AB$: CE, and $CE = \frac{AB}{c}$, and $cE^2 = \frac{ABc}{c^2}$. Therefore Dm $= \frac{AB^2}{c^2 \times CD}, = \frac{L^2}{9{,}87CD}$ nearly.

We can now tell the number of vibrations made in a second by a string. This we obtain by comparing its motion, when impelled by the accelerating force which acts on it, with its motion when acted on by its weight only. Therefore let L be the length of a string, and W its weight, and let E be the straining weight, or extending force. Let f be the force which accelerates the particle Dd of the cord, and w the weight of that particle, while W is the weight of the whole cord. Let z the space which the particle Dd would describe during the time of one vibration by the uniform action of the force f, and let S be the space which it would describe in the same time by its weight w alone. Then (Dynamics, *Suppl.* n° 103. cor. 6.) the time in which f would impel the particle Dd along $\frac{1}{2}$ DC, is to the time of one vibration as $1 : c$. And $\frac{1}{2}$ DC is to z as the square of the time of describing $\frac{1}{2}$ DC, is to the square of the time of describing z; that is, $1 : c^2 = \frac{1}{2}DC : 2z$, and $c^2.DC = 2z$.

Now, by the property of the harmonic curve,

$$AB : Dm = 2z : AB$$
$$\text{But } Dm : Dd = E : f$$
$$\text{And } Dd : AB = w : W$$
$$\text{Therefore } 2z \cdot E \cdot w = AB \cdot f \cdot W$$
$$\text{And } f : w = 2z \times E : AB \times W$$
$$\text{But } w : f = 2S : 2z$$
$$\text{Therefore } 2S \times E = AB \times W$$
$$\text{And } 2E : W = AB : S.$$

That is, a musical cord, extended by a force E, performs one vibration DCV in the time that a heavy body describes a space S, which is to the length of the cord as its weight is to twice the extending force.

Now let g be the space through which a heavy body falls in one second, and let the time of a vibration (estimated in parts of a second) be T. We have

$$AB : S = 2E : W$$
$$S : g = T^2 : 1^2$$
$$\text{Therefore } AB : g = 2E \cdot T^2 : W$$
$$\text{And } AB \times W = T^2 \times 2E \times g$$
$$\text{Therefore } T^2 = \frac{AB \times W}{2g.E}, \text{ and } T = \sqrt{\frac{AB \times W}{2g.E}}$$

Let n be the number of vibrations made in a second.

$$n = \frac{1}{T}, = \sqrt{\frac{2g.E}{AB.W}} = \sqrt{\frac{2g\,E}{L.W}}.$$

If the length of the cord be measured in feet, $2g$ is very nearly 32. If in inches, $2g$ is 386, more nearly. Therefore $n = \sqrt{\frac{32\,E}{L \cdot W}}$ or $\sqrt{\frac{386\,E}{L \cdot W}}$. This may easily be compared with observation. Dr Smith hung a weight of 7 pounds, or 49,000 grains, on a brass wire suspended from a finger pin, and shortened it till it was in perfect unison with the double octave below the open string D of a violin. In this state the wire was 35,55 inches long, and it weighed 31 grains.

Now $\sqrt{\frac{384 \times 49000}{35{,}55 \times 31}} = 130{,}7 = n$. This wire, therefore, ought to make 130,7 vibrations in a second. Dr Smith proceeded to ascertain the number of aereal pulses made by this sound, availing himself of the theory of the beats of tempered consonances invented by himself. On his fine chamber organ he tuned upwards the perfect fifths DA, A e, e b, and then tuned downward the perfect 6th e d. Thus he obtained an octave to D, which was too sharp by a comma, and he found that it beat 65 times in 20 seconds. Therefore the number of vibrations was $\frac{65}{20}$ 81, or 263,25. These were complete pulses or motions from D to V and back again, and therefore contained 526½ such vibrations as we have now been considering. The double octave below should make ¼th of this, or 131,6, which is not a complete vibration more than the above theory requires: more accurate coincidence is needless.

This theory is therefore very completely established, and it may be considered as one of the finest mechanical problems which has been solved in this century. We mention it with the greater minuteness, because the merit of Dr Taylor is not sufficiently attended to. Mr Rameau, and the other great theorists in music, make no mention of him; and such as have occasion to speak of the absolute number of vibrations made by any musical note, always quote Mr Sauveur of the French academy.

2

demy. This gentleman has written some very excellent dissertations on the theory of music, and Sir Isaac Newton in his *Principia* often quotes his authority. He has given the actual determination of the number of vibrations of the note C, obtained in a manner similar to that practised by Dr Smith on his chamber organ, and which agrees extremely well with that measure. But Mr Sauveur has also given a mechanical investigation of the problem, which gives the same number of vibrations that he observed. We presume that Rameau and others took the demonstration for good; and thus Mr Sauveur passes on the Continent for the discoverer of this theorem. But it was not published till 1716, though read in 1713; whereas Dr Taylor's demonstration was read to the Royal Society in May 1714. But this demonstration of Mr Sauveur is a mere paralogism, where errors compensate errors; and the assumption on which he proceeds is quite gratuitous, and has nothing to do with the subject. Yet John Bernoulli, from enmity to Taylor and the English mathematicians, takes not the least notice of this sophisticated demonstration, accommodated to the experiment, and so devoid of any pretensions to argument that this severe critic could not but see its falsity.

Sauveur was one of the first who observed distinctly that remarkable fact which Mr Rameau made the foundation of his musical theory, *viz.* that a full musical note is accompanied by its octave, its twelfth, and its seventeenth major. It had been casually observed before, by Marsennus, by Perrault, and others; but Sauveur tells distinctly how to make the observation, and affirms it to be true in all deep notes. Rameau asserts it to be universally and necessarily true in all notes, and the foundation of all musical pleasure.

It had been discovered before this time, that not only a full note caused its unison to resound, but also that a 12th, being sounded near any open string, the string *resounded* to this 12th. It does the same to a 15th, a 17th major, a 22d, &c.

Dr Wallis added a very curious circumstance to this observation. Two of his pupils, Mr Noble and Mr Pigott, in 1673, amusing themselves with these resonances, observed, that if a small bit of paper be laid on the string of a violin which is made to resound to its unison, the paper is thrown off: a proof that the string resounded by really vibrating, and that it is thrown into these vibrations by the pulses of the air produced by the other string. In like manner the paper is thrown off when the string resounds to its octave. But the young gentlemen observed, that when the paper was laid on the middle point of the string, it remained without agitation, although the string still resounded. They found the same thing when they made the string resound to its 12th: papers laid on the two points of division lay still, but were thrown off when laid on any other place. In short, they found it a general rule, that papers laid on any points of division corresponding to the note which was resounded, were not agitated.

Dr Wallis (the greatest theorist in music of the last century) justly concluded that these points of the resounding string were at rest, and that the intermediate parts were vibrating, and producing the notes corresponding to their lengths.

From this Mr Sauveur, with great propriety, deduced the theory of the performance of the trumpet marine, the vielle, the clavichord, and some other instruments.

When the string of the trumpet marine is gently stopped at $\frac{1}{2}$, and the bow drawn lightly across it at H (fig. A), the full vibration at the finger is stopped; but the string is thrown into vibrations of some kind, which will either be destroyed or may go on. It is of importance to see what circumstance will permit their continuance.

Suppose an elastic cord put into the situation ABCDE (fig. D), such that AB, BC, CD, DE, are all equal, and that BCD is a straight line. Let the point C be made fast, and the two points B and D be let go at once. It is evident that the two parts will immediately vibrate in two harmonical curves A*b*C and CDE, which will change to ABC and C*d*E, and so on alternately. It is also evident that if a line FCG be drawn touching the curve ABC, it will also touch the curve CDE; and the line which touches the curve A*b*C in C, will also touch the curve C*d*E. In every instant the two halves of the cord will be curves which have a common tangent in the point C. The undoubted consequence of this is, that the point C will not be affected by these vibrations, and its fixure may be taken away. The cord will continue to vibrate, and will give the sound of the octave to its fundamental note.

The condition, then, which must be implemented, in order that a string may resound to its octave, or take the sound of its octave, is simply this, that its two parts may vibrate equally in opposite directions. This is evidently possible; and when the bow is drawn across the string of the trumpet marine at H, and irregular vibrations are produced in the whole string, those which happen to be in one direction on both sides of the middle point, where it is gently stopped by the finger, will destroy each other, and the conspiring ones will be instantly produced, and then every succeeding action of the bow will increase them.

The same thing must happen if a string is gently stopped at one-third of its length; for there will be the same equilibrium of forces at the two points of division, so that the fixures of these points may be removed, and the string will vibrate in three parts, sounding the 12th of the fundamental.

We may observe, by the way, that if the bow be drawn across the string at one of the points of division, corresponding to the stopping at the other end of the string, it will hardly give any distinct note. It rattles, and is intolerably harsh. The reason is plain: The bow takes some hold of the point C, and drags it along with it. The cord on each side of C is left behind, and therefore the two curves cannot have a common tangent at C. The vibrations into which it is thus jogged by the bow destroy each other.

We now see why the trumpet marine will not sound every note. It will sound none but such as correspond to a division of the string into a number of equal parts, and its note will be in unison with a string equal to one of those parts. Therefore it will *first* of all sound the fundamental, by its whole length;

2. Its octave, corresponding to its length
3. The 12th, - - -
4. The 15th, or double octave, $\frac{1}{4}$
5. The 17th, - - - $\frac{1}{5}$
6. The 19th, - - $\frac{1}{6}$

7. The

Musical Trumpet

7. The 21st, which is not in the diatonic scale of our music, - $\frac{1}{7}$ its length.
8. The triple octave, or 22d, - $\frac{1}{8}$
9. The 23d, or 2d in the scale of the triple octave - - - $\frac{1}{9}$
10. The 24th, or 3d in this scale, $\frac{1}{10}$
11. The 25th, a false 4th of this scale, $\frac{1}{11}$
12. The 26th, a perfect 5th of this scale, $\frac{1}{12}$
13. The 27th, a false 6th of ditto, $\frac{1}{13} = \frac{1}{13}$ or [illegible]
14. The 28th, a false 7th minor, - $\frac{1}{14}$
15. The 28th, a perfect 7th major, $\frac{1}{15}$
16. The quadruple octave, - $\frac{1}{16}$

Thus we see that this instrument will not execute all music, and indeed will not complete any octave, because it will neither give a perfect 4th nor 6th. We shall presently see that these are the very defects of the trumpet.

This singular stringed instrument has been described in this detail, chiefly with the view of preparing us for understanding the real trumpet. The VIELLE, SAVOYARDE, or HURDYGURDY, performs in the same manner. While the wheel rubs one part of the string like a bow, the keys gently press the strings, in points of aliquot division, and produce the harmonic notes.

It is to prevent such notes that the part of harpsichord wires, lying between the bridge and the pins, are wrapped round with list. These notes would frequently disturb the music.

Lastly on this head, the Æolian harp derives its vast variety of fine sounds from this mode of vibration. Seldom do the cords perform their fundamental or simple vibrations. They are generally sounding some of the harmonics of their fundamentals, and give us all this variety from strings tuned in unison.

TRUMPET, Musical, is a wind instrument which sounds by pressing the closed lips to the small end, and forcing the wind through a very narrow aperture between the lips. This is one of the most ancient of musical instruments, and has appeared in all nations in a vast variety of forms. The conch of the savage, the horn of the cowherd and of the postman, the bugle horn, the lituus and tuba of the Romans, the military trumpet, and the trombone, the *cor de chasse* or French horn—are all instruments winded in the same manner, producing their variety of tones by varying the manner and force of blowing. The serpent is another instrument of the same kind, but producing part of its notes by means of holes in the sides.

Although the trumpet is the simplest of all musical instruments, being nothing but a long tube, narrow at one end and wide at the other, it is the most difficult to be explained. To understand how sonorous and regulated undulations can be excited in a tube without any previous vibration of reeds to form the waves at the entry, or of holes to vary the notes, requires a very nice attention to the mechanism of aereal undulations, and we are by no means certain that we have as yet hit on the true explanation. We are certain, however, that these aereal undulations do not differ from those produced by the vibration of strings; for they make strings resound in the same manner as vibrating cords do. Galileo, however, did not know this argument for his assertion that the musical pitch of a pipe, like that of a cord, depended on the frequency alone of the aereal undulations; but he thought it highly probable, from his observations on the structure of organs, that the notes of pipes were related to their lengths in the same manner as those of wires, and he expressly makes this remark. Newton, having discovered that sound moved at the rate of about 960 feet per second, observed that, according to the experiments of Mr Sauveur, the length of an open pipe is half the length of an aereal pulse. This he could easily ascertain by dividing the space described by sound in a second by the number of pulses.

Daniel Bernoulli, the celebrated promoter of the Newtonian mechanics, discovered, or at least was the first who attentively marked, some other circumstances of resemblance between the undulations of the air in pipes and the vibrations of wires. As a wire can be made, not only to vibrate in its full length, sounding its fundamental note, but can also be made to subdivide itself, and vibrate like a portion of the whole, with points of rest between the vibrating portions, when it gives one of its harmonic notes; so a pipe cannot only have such undulations of air going on within it as are competent to the production of its fundamental note, but also those which produce one of its harmonic notes. Every one knows that when we force a flute, by blowing too strongly, it quits its proper note, and gives the octave above. Forcing still more, produces the 12th. Then we can produce the double octave or 15th, and the 17th major, &c. In short, by attending to several circumstances in the manner of blowing, all the notes may be produced from one very long pipe that we produce from the trumpet marine, and in precisely the same order, and with the same omissions and imperfections. This alone is almost equivalent to a proof that the mechanism of the undulations of air in a pipe are analogous to that of the vibrations of an elastic cord. Having with so great success investigated the mechanism of the partial vibrations of wires, and also another kind of vibrations which we shall mention afterwards, incomparably more curious and more important in the philosophy of musical sounds, Mr Bernoulli undertook the investigation of those more mysterious motions of air which are produced in pipes; and in a very ingenious dissertation, published in the Memoirs of the Academy of Paris for 1762, &c. he gives a theory of them, which tallies in a wonderful manner with the chief phenomena which we observe in the wind instruments of the flute and trumpet kind. We are not, however, so well satisfied with the truth of his *assumptions* respecting the state of the air, and the precise form of the undulations which he assigns to it; but we see that, notwithstanding a probability of his being mistaken in these circumstances (it is with great deference that we presume to suppose him mistaken), the chief propositions are still true; and that the changes from note to note must be produced in the order, tho' perhaps not in the precise manner, assigned by him.

It is by no means easy to conceive, with clearness, the way in which musical undulations are excited in the various kinds of trumpets. Many who have reputation as mechanicians, suppose that it is by means of vibrations of the lips, in the same manner as in the hautboy, clarionette, and reed pipes of the organ, where the air, say they, is put in motion by the trembling reed. But this explanation is wrong in all its parts; even in the reed pipes of an organ, the air is not put in motion by the reeds. They are indeed the *occasions* of its musical undulation, but they do not *immediately impel* it into

Musical Trumpet.

into those waves. This method (and indeed all methods but the vibrations of wires, bells, &c.) of producing sound is little understood, though it is highly worthy of notice, being the origin of animal voice, and because a knowledge of it would enable the artists to entertain us with sounds hitherto unknown, and thus add considerably to this gift of our Bountiful Father, who has shewn, in the structure of the larynx of the human species, that he intended that we should enjoy the pleasures of music as a *laborum dulce lenimen*. He has there placed a micrometer apparatus, by which, *after* the other muscles have done their part in bringing the glottis nearly to the tension which the intended note requires, we can easily, and instantly, adjust it with the utmost nicety.

We trust, therefore, that our readers will indulge us while we give a very cursory view of the manner in which the tremulous motion of the glottis, or of a reed in an organ pipe, produces the sonorous undulations with a constant or uniform frequency, so as to yield a musical note.

If we blow through a small pipe or quill, we produce only a whizzing or hissing noise. If, in blowing, we shut the entry with our tongue, we hear something like a solid blow or tap, and it is accompanied with some faint perception of a musical pitch, just as when we tap with the finger on one of the holes of a flute when all the rest are shut. We are then sensible of a difference of pitch according to the length of the pipe; a longer pipe or quill giving a graver sound. Here, then, is like the *beginning* of a sonorous undulation. Let us consider the state of the air in the pipe: It was filled by a column of air, which was moving forward, and would have been succeeded by other air in the same state. This air was therefore nearly in its state of natural density. When the entry is suddenly stopped by the tongue, the included air, already in motion, conti- its motion. This it cannot do without growing rarer, and then it is no longer a balance for the pressure of the atmosphere. It is therefore retarded in its motion, totally stopped (being in a rarefied state), and is then pressed back again. It comes back with an accelerated motion, and recovers its natural density, while the state of rarefaction goes forward through the open air like any other aereal pulse. Its motions are somewhat, but not altogether, like that of a spiral wire, which has been in like manner moving uniformly along the pipe, and has been stopped by something catching hold of its hindermost extremity. This spring, when thus catched behind, stretches itself a little, then contracts *beyond* its natural state, and then expands again, quivering several times. It can be demonstrated that the column of air will make but one quiver. Suppose this accomplished in the hundredth part of a second, and that at that instant the tongue is removed for the hundredth part of a second, and again applied to the entry of the pipe. It is plain that this will produce such another pulse, which will join to the former one, and force it out into the air, and the two pulses together will be like two pulses produced by the vibration of a cord. If, instead of the tongue, we suppose the flat plate of an organ-reed to be thus alternately applied to the hole and removed, at the exact moments that the renewals of air are wanted, it is plain that we shall have *sonorous* undulations of *uniform* frequency, and therefore a musical note. This is the way in which reeds produce their effect, not by *impelling* the air into alternate states of motion to and fro, and alternate strata of rarefied and condensed air, but by giving them time to acquire this state by the combination of the air's elasticity with its progressive motion.

The adjustment of the succeeding puff of air to the pulse which precedes it, so that they may make — smooth and regular pulse, is more exact than we have yet remarked; for the stoppage of the hole not only *occasions* a rarefaction *before it*, but by checking the air which was just going to enter, makes a condensation *behind the door* (so to speak); so that, when the passage is again opened, the two parcels of air are fitted for supporting each other, and forming one pulse.

Suppose, in the next place, that the reed, instead of completely shutting the hole each time, only half shuts it. The same thing must still happen, although not in so remarkable a degree. When the passage is contracted, the supply is diminished, and the air now in the pipe must rarefy, by advancing with its former velocity. It must therefore retard; by retarding, regain its former density; and the air, not yet got into the pipe, must condense, &c. And if the passage be again opened or enlarged in the proper time, we shall have a complete pulse of condensed and rarefied air; and this must be accompanied by the beginning of a musical note, which may be continued like the former.

This will be a softer or more mellow note than the other; for the condensed and rarefied air will not be so suddenly changed in their densities. The difference will be like the difference of the notes produced by drawing a quill along the teeth of a comb, and that produced by the equally rapid vibrations of a wire. For let it be remarked here, that musical notes are by no means confined, as theorists commonly suppose, to the regular cycloidal agitations of air, such as are produced by the vibrations of an elastic cord; but that any crack, snap, or noise whatever, when repeated with sufficient frequency, becomes *ipso facto* a musical sound, of which we can tell the pitch or note. What can be less musical than the solitary cracks or snaps made by a stiff door when very slowly opened? Do this briskly, and the creak changes to a chirp, of which we can tell the note. The sounds will be harsh or smooth, according as the snaps of which they are composed are abrupt or gradual.

This distinction of sounds is most satisfactorily firmed by experiment. If the tongue of the organ ree quite flat, and if, in its vibrations, it apply itself t whole margin of the hole at once, so as complet shut it (as is the case in the oldfashioned regal the organ), the note is clear, smart, and harsh or but if the lips of the reed are curved, or the t properly bent backward, so that it applies itself t edges of the hole *gradatim*, and never completely the passage, the note may have any degree of m sweetness. This remark is worth the attention of instrument-makers or organ builders, and enables th to vary the VOICE of the organ at pleasure. We only mention it here as introductory to the explanation of the sounds of the trumpet.

We trust that the reader now perceives how the air, proceeding along a pipe, may be put in the state of alternate strata of condensed and rarefied air, the particles, in the mean time, proceeding along the pipe with a very moderate velocity; while the *state of undulation* is propagated at the rate of eleven or twelve hundred feet

Musical Trumpet.

feet in a second; just as we may sometimes see a stream of water gliding gently down a canal, while a wave runs along its surface with much greater rapidity.

It will greatly assist the imagination, if we compare these aëreal undulations with the undulations of water in an open canal. While the water is flowing smoothly along, suppose a sluice to be thrust up from the bottom quite to the surface, or beyond it. This will immediately cause a depression on the lower side of the sluice, by the water's going along the canal, and a heaping up of the water on the other side. By properly timing the motion of this sluice up and down, we can produce a series of connected waves. If the sluice be not pushed up to the surface but only one-half way, there will be the same succession of waves, but much smoother, &c. &c.

It is in this state, though not by such means, that the air is contained in a sounding trumpet. It is not brought into this state by any tremor of the lips. The trumpeter sometimes feels such a tremor; but whenever he feels it, he can no longer sound his note. His lips are painfully tickled, and he must change his manner of winding.

When blowing with great delicacy and care, the deepest notes of a French horn, or trombone, we sometimes can feel the undulations of the air in the pipe distinctly fluttering and beating against the lips; and it is difficult to hinder the lips from being affected by it: but we feel plainly that it is not the lips which are fluttering, but the air before them. We feel a curious instance of this when we attempt to whistle in concert. If our accompanier intonates with a certain degree of incorrectness, we feel something at our own lips which makes it impossible to utter the intended note. This happens very frequently to the person who is whistling the upper note of a greater third. In like manner, the undulations in a pipe react on the reed, and check its vibrations. For if the dimensions of a pipe are such that the undulations formed by the reed cannot be kept up in the pipe, or do not suit the length of the pipe, the reed will either not play at all, or will vibrate only in starts. This is finely illustrated by a beautiful and instructive experiment. Take a small reed of the *vox humana* stop of an organ, and set it in a glass foot, adapted to the windbox of the organ. Instead of the com pipe above it, fix on it the sliding tube of a small scope. When all the joints are thrust down, touch key, and look attentively to the play of the reed. While it is sounding, draw out the joints, making the pipe continually longer. We shall observe the reed thrown into strange fits of quivering, and sometimes quite motionless, and then thrown into wide sonorous vibrations, according as the *maintainable* pulse is com ite or not with the vibrations of the reed. This shews that the air is not impelled into its undu is by the reed, but that the reed accommodates it to the undulations in the pipe.

We acknowledge that we cannot explain with distinctness in what manner the air in a trumpet is first put into musical undulations. We see that it is only in very long and slender tubes that this can be done. In short tubes, of considerable diameter, like the cowherd's horn, we obtain only one or two very indistinct notes, of which it is difficult to name the pitch; this requires great force of blast; whereas, to bring out the deep notes of the French horn, a very gentle and well regulated blast is necessary. The form of the lips, combined with the force of the blast, form all the notes. But this is in a way that cannot be taught by any description. The performer learns it by habit, and *feels* that the instrument leaps into its note without him, when he gradually varies his blast, and continues sounding the same note; although he, in the mean time, makes some small change in his manner of blowing. This is owing to what Mr Bernoulli observed. The tube is suited only to such pulses, and can only maintain such pulses as correspond to aliquot parts of its length; and when the embouchure is very nearly, but not accurately, suited to a particular note, that note *forms itself* in the tube, and, reacting on the lips, brings them into the form which can maintain it with ease. We have a proof of this when we attempt to sound the note corresponding to one seventh of the length. Not having a distinct notion of this note, which makes no part of our scale of melody, we cannot easily prepare for it in the way that habit teaches us to prepare for the others: whereas, from what we shall see presently, the notes *one-sixth* and *one eighth* are both familiar to the mind, and easily produced. When, therefore, we attempt to produce the note *one-seventh*, we slide, against our will, into the *one sixth* or *one-eighth*.

Nor can we completely illustrate the formation of musical pulses by waves in water. A canal is equally susceptible of every height and length of progressive waves; whereas we see that a certain length of tube will maintain only certain determined pulses of air.

We must therefore content ourselves for the present with having learned, by means of the reed pipes, how the air may exist progressively in a tube, in an alternate state of condensation and rarefaction; and we shall now proceed to consider how this state of the air is related to the length of the tube. And here we can do no more than give an outline of Mr Bernoulli's beautiful theory of flutes and trumpets, but without a mathematical examination of the particular motions. We can, however, shew, with sufficient evidence, how the different notes are produced from the same tube. It requires, however, a very steady attention from the reader to enable him to perceive how the different portions of this air act on each other. We trust that this will now be given.

The conditions which must be implemented, in order to maintain a musical pulse, are two: 1. That the vibrations of the different plates of air be performed in equal times, otherwise they would all mix and confound each other. 2. That they move all together, all beginning and all ending at the same instant. It does not appear that any other state of vibration can exist and be maintained.

The column of air in a tube may be considered as a material spring (having weight and inertia) This spring is compressed and coiled up by the pressure of the atmosphere. But in this coiled state it can vibrate in its different parts, as a long spiral wire may do, though pressed a little together at the ends. It is evident that the air within a pipe, shut at both ends, may be placed in such a situation, *in a variety of ways*, that it will vibrate in every part, in the same manner as a chord of the same length and weight, strained by a force equal to the pressure of the atmosphere. Thus, in the shut pipe AB (fig. 1.), suppose a harmonic curve ACB, or a wire

Plate XLV.

a wire of the same weight with the air, throwing itself into the form of this curve. The force which impels the point C to the axis is to that which impels the point c as CE to ce. Now, suppose the air in this pipe divided into parallel strata or plates, crossing the tube like diaphragms. In order that these may vibrate in the same manner (not across the tube, but in the direction of its axis), all that is necessary for the moment is, that the excess of the pressure of the stratum dd above that of the stratum ff may be to the excess of the pressure of DD above that of FF as ce to CE. In this case, the stratum ce will be accelerated in the direction ef, and the stratum EE is accelerated in the same direction, and in the due proportion. Now this may be done in an infinite variety of ways for a single moment. It depends, not on the absolute density, but on the *variation* of density; because the pressure by which a particle of air is urged in any direction arises from the *difference* of the distances of the adjoining particles on each side of it. But in order to *continue* this vibration, or in order that it may obtain at once in the whole pipe, this variation of density must continue, and be according to some connected law. This circumstance greatly limits the ways in which the vibration may be kept up. Mr Bernoulli finds that the isochronism and synchronism can be maintained in the following manner, and in no other that he could think of:

Let AB (fig. 2.) be a cylindrical pipe, shut at A, and open at B. Then, in whatever manner the sound is produced in the pipe, the undulations of the contained air must be performed as follows: Let aa be a plate of air. This plate will approach to, and recede from, the shut end A, vibrating between the situations bb and cc, the whole vibration being bc, and the plate will vibrate like a pendulum in a cycloid. The greater we suppose the excursions ab, ac, the louder will the sound be; but the duration of them all must be the same, to agree with the fact that the tone remains the same. The motion will be accelerated in approaching to aa from either side, and retarded in the recess from it. Let us next consider a plate $\alpha\alpha$, more remote from A. It must make similar vibrations from the situation $\beta\beta$ to the situation $\gamma\gamma$. But these vibrations must be greater in proportion as the plate is farther from A. It cannot be conceived otherwise: For suppose the plate $\alpha\alpha$ to make the *same* excursions with aa, and that the rest do the same. Then they will all retain the same distances from each other; and thus there will be no force whatever acting on any particles to make them vibrate. But if every particle make excursions proportional to its distance from A, the *variation* of density will, in any instant, be the same through the whole pipe, and each particle in the vibrating plate $\beta\beta$ will be accelerated or retarded in proportion to its distance from A; while the accelerations and retardations over all will, in any instant, be proportional to the distance of each particle from its place of rest. All this will appear to the mathematician, who attentively considers any momentary situation of the particles. In this manner all the particles will support each other in their vibrations.

It follows from this description that the air in the tube is alternately rarefied and condensed. But these changes are very different in different parts of the tube. They must be greatest of all at A; because, while all the plates approach to A, they concur in condensing the air immediately adjoining to A; while the air in aa and $\alpha\alpha$ is less condensed by the action of the plates beyond it. The air at B is always of its natural density, being in equilibrio with the surrounding air. At B, therefore, there is a small parcel of air, of its natural density, which is alternately going in and out.

This account is confirmed by many facts. If the bottom of the pipe be shut by a fine membrane, stretched across it like a drumhead, with a wire stretched over it either externally or internally, in the same manner as the catgut is stretched across the bottom of a drum, it will be thrown into strong vibrations, making a very loud noise, by rattling against the cross wire. The same thing happens if the membrane be pasted over a hole close to the bottom, leaving a small space round the edge of the hole without paste, so that the membrane may play out and in, and rattle on the margin of the hole. This also makes a prodigious noise. Now, if the membrane be pasted on a hole far from the bottom, the agitations will be much fainter; and when the hole is near the mouth of the pipe, there will be none.—When a pipe has its air agitated in this manner, it is giving the lowest note of which it is susceptible.

Let us next consider a pipe open at both ends. Let CB (fig. 3.) be this pipe. It is plain that, if there be a partition A in the middle, we shall have two pipes AB, AC, each of which may undulate in the manner now described, if the undulations in each be in opposite directions. It is evidently possible, also, that these undulations may be the same in point of strength in both, and that they may begin in the same instant. In this case, the air on each side of the partition will be in the same state, whether of condensation or rarefaction, and the partition A itself will always be in equilibrio. It will perfectly resemble the point C of the musical cord BFCGH (fig. 6.), which is in equilibrio between the vibrating forces of its two parts. In the pipe, the plates of air on each side are either both approaching it, or both receding from it, and the partition is either equally squeezed from both sides, or equally drawn outwards. Consequently this partition may be removed, and the parcels of air on each side will, in any instant, support each other. There seems no other way of conceiving these vibrations in open pipes which will admit of an explanation by mechanical laws. The vibrations of all the plates must be obtained without any mutual hinderance, in order to produce the tone which we really hear; and therefore such vibrations are impressed by Nature on each plate of air.

But if this explanation be just, it is plain that this pipe CB must give the same note with the pipe AB (fig. 2.) of half the length, shut at one end. But the sound, being doubled, with perfect consonance, must be clear, strong, and mellow. Now this is perfectly agreeable to observation; and this fact is an unequivocal confirmation of the justness of the theory. If we take a slender pipe, about six inches long and one half of an inch wide, shut at one end, and sound it by blowing across its mouth, as we whistle on the pipe of a key, or across a hole that is close to the mouth, and formed with an edge like the sound-hole of a German flute, we shall get a very distinct and clear tone from it. If we now take a pipe of double the length, open at both ends, and blow across its mouth, we obtain the same note, but more clear and strong. And the note produced by blowing across the mouth is not changed by a hole made exactly in the middle, in respect of its musical

pitch

Musical Trumpet

pitch, although it is greatly hurt in point of clearness and strength. Also a membrane at this hole is strongly agitated. All this is in perfect conformity to this mechanism.

Thus we have, in a great measure, explained the effect of an open and a shut pipe. The shut pipe is always an octave, graver than an open pipe of the same length; because the open pipe is in unison with a shut pipe of half the length.

Let AC (fig. 4.) be a pipe shut at both ends. We may consider it as composed of two pipes AB, BC, stopped at A and C, and open at B. Undulations may be performed in each half, precisely as in the pipe AB of fig. 2.; and they will not, in the smallest degree, obstruct each other, if we only suppose that the plates in each half are vibrating at once in the *same* direction. The condensation in AB will correspond with the rarefaction in BC, and the middle parcel B will maintain its natural density, vibrating to, and again across the middle; and two plates *a a*, *α α*, which are equally distant from B, will make equal excursions in the same direction.

We may produce sound in this pipe by making an opening at B. Its note will be found to be the same with that of BC of fig. 2. or of AB of fig. 2.

In the next place, let a pipe, shut at one end, be considered as divided into any odd number of equal parts, and let them be taken in pairs, beginning at the stopped end, so that there may be an odd one left at the open end. It is plain that each of these pairs may be considered as a pipe stopped at both ends, as in fig. 4.

For the partitions will, of themselves, be in equilibrio, and may be removed, and vibrations may be maintained in the whole, consistent with the vibration of the odd part at the open end; and these vibrations will all support each other, and the plates of air which are at the points of division will remain at rest. Conceive the pipe AB of fig. 2. to be added to the pipe AC of fig. 4. the part A of the first being joined to A of the other. Now, suppose the vibrations to be performed in both, in such a manner that the simultaneous undulations on each side of the junction may be in opposite directions. It is plain that the partition will be in equilibrio, and may be removed; and the plate of air will perform the same office, being alternately the middle plate of a condensed and of a rarefied parcel of air. The two pipes CA, AB will together give the same note that AB would have given alone, but louder.

In like manner may another pipe, equal to AC, be joined to the shut end of this compound pipe, as in fig. 5. and the three will still give the same note that AB would have done alone.

And in the same manner may any number of pipes, each equal to AC, be added, and the whole will give still the same note that AB would have given alone.

Hence it legitimately follows, that if the undulations can be once begun in this manner in a pipe, it may give either the sound competent to it, as a single pipe AB (fig. 2.); or it may give the sound competent to a pipe of $\frac{1}{3}$d, $\frac{1}{5}$th, $\frac{1}{7}$th, &c. of its length; the undulations in each part AB, BC, CD, maintaining themselves in the manner already described. This seems the only way in which they can be preserved, both isochronous and synchronous.

It is known that the gravest tones of pipes are as the lengths of the pipes, or the frequency of the undulations are inversely as their lengths. (This will be *demonstrated* presently). Therefore these accessory tones should be as the odd numbers 3, 5, 7, &c. and the whole tones, including the fundamental, should form the progression of the odd numbers 1, 3, 5, 7, &c.

This is abundantly confirmed by experiment. Take a German flute, and stop all the finger holes. The flute, by gradually forcing the blast, will give the fundamental, the 12th, the 17th, the 21st, &c. (A).

Again, let AD (fig. 6.) represent the length of a pipe. Construct on AD an harmonic curve AEBFCGHD, in such a manner that HD may be $\frac{1}{2}$ AB, $= \frac{1}{2}$ BC, $= \frac{1}{2}$ CH. The small ordinates *m n* will express the total excursion of the plates of air at the points *m*, *m*, &c. and those ordinates which are above the axis will express excursions on one side of the place of rest, and the ordinates below will mark the excursions in the opposite directions, in the same manner as if this harmonic curve were really a vibrating cord. These excursions are nothing in the points A, B, C, H, and are greatest at the points E, F, G, D, where the little mass of air retains its natural density, and travels to and again, condensing the air at B, or rarefying it, according as the parcels E and F are approaching to or receding from each other. The points A, B, C, H, may be called Nodes, and the parts E, F, G, D, may be called Bights or Loops. This represents very well to the eye the motion of the plates of air. The density and velocity need not be minutely considered at present. It is enough that we see that when the density is increasing at A, by the approach of the parcel E, it is diminishing at B by the recess of E and F; and increasing at C, by the approach of F and G, and diminishing at H, by the recess of G. In the next vibration it will be diminishing at A and C, and increasing at B and H. And thus the alternate nodes will be in the same state, and the adjoining nodes in opposite states.

The reader must carefully distinguish this motion from

(A) A little reflection will teach us that these tones will not be perfectly in the scale. A certain proportion between the diameter and length of the pipe produces a certain tone. Making the pipe wider or smaller flattens or sharpens this tone a little, and also greatly changes its clearness. Organ-builders, who have tried every proportion, have adopted what they found best. This requires the diameter to be about $\frac{1}{10}$th or $\frac{1}{12}$th of the length. Therefore, when we cause the same pipe to sound different notes, we neglect this proportion; and the notes are false, and even very coarse, when we produce one corresponding to a very small portion of the pipe. For a similar reason, Mr Lambert found that, in order to make his pitch-pipe sound the octave to any of its notes, it was not sufficient to shorten its capacity one-half by pushing down the piston; he found that the part remaining must be less than the part taken off by a fixed quantity $1\frac{1}{5}$ inches. Or, the length which gave any note being *a*, the length for its octave must be $\frac{a - 1\frac{1}{5}}{2}$.

Musical Trumpet.

from the undulatory motion of a pulse, investigated by Newton, and described in the article ACOUSTICS, *Encycl.* That undulation is going on at the same time, and is *a result* of what we are now considering, and the cause of our hearing this undulation. The undulation we are now considering is the original agitation, or rather it is the SOUNDING BODY, as much as a vibrating string or bell is; for it is not the trumpet that we hear, but the air trembling in the trumpet. The trumpet is performing the office, not of the string, but of the pin and bridge on which the string is strained. This is an important remark in the philosophy of musical sounds.

There is yet another set of notes producible from a pipe besides those which follow in the order of frequency 1, 3, 5, 7, &c.

Suppose a pipe open at both ends, sounding by blowing across the end, and undulating, as already described, with a node in the middle A (fig. 3.) If we still express the fundamental note of the pipe AB of fig. 2. by 1, it is plain that the fundamental of an open pipe of the same length will have the frequency of its undulations expressed by 2; because an open pipe of twice the length of AB (fig 2.) will be 1, the two pipes AB (fig. 2.), and CB (fig. 3), being in unison.

But this open pipe may be made to undulate in another manner; for we have seen that AC of fig. 2. joined to CA of fig. 4. may sound altogether when the partition A is removed, still giving the note of AB (fig. 2.) Let such another as AB (fig. 2.) be added to the end C, and let the partition be removed. The whole may still undulate, and still produce the same note; that is, a pipe open at both ends may sound a note which is the fundamental of a pipe like AB (fig. 2.), but only one-fourth of its length. The pipe CB of fig. 3. may thus be supposed to be divided into four equal parts, CE, EA, AF, FB, of which the extreme parts EC and FB contain undulations similar to those in AB (fig. 2.); and the two middle parts contain undulations like those in CA (fig. 4.) The partitions at E and F may be removed, because the undulations in EC and EA will support each other, if they are in opposite directions; and those in FB and FA may support each other in the same manner.

It must here be remarked, that in this state of undulation the direction of the agitations at the two extremities is the same; for in the middle piece EF the particles are moving one way, condensing the air at E, while they rarefy it at F. Therefore, while the middle parcel is moving from E towards F, the air at B must be moving towards F, and the air at C must be moving from E. In short, the air at the two extremities must, in every instant, be moving in the opposite direction to that of the air in the middle.

In like manner, if the pipe CB of fig. 3. be divided into six parts, the two extreme parts may undulate like AB of fig. 2. and the four inner parts may undulate like two pipes, such as CA of fig 4. and the whole will give the sound which makes the fundamental of a pipe of one sixth of the length, or having the frequency 6.

We may remark here, that the simultaneous motion of the air at the extremities is in opposite directions, whereas in the last case it was in the same direction. This is easily seen; for as the partition which is between the two middle pieces must always be in equilibrio, the air must be coming in or going out at the extremities together. This circumstance must give some sensible difference of character to the sounds 4 and 6. In the one, the agitations at each end of the tube are in the same direction, and in the other they are in the opposite. Both produce pulses of sound which are conveyed to the ear. Thus we see that the air in a pipe open at both ends may undulate in two ways. It may undulate with a node in the middle, giving the note of AB (fig. 2.), or of its 3d, 5th, 7th, &c. past; and it may undulate with a loop or bight in the middle, sounding like $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{6}$, &c of AB, fig. 2.

Musical Trumpet.

In like manner may this pipe produce sounds whose frequency are expressed by 8, 10, &c. and proceed as the even numbers.

This state of agitation may be represented in the same way that we represented the sounds 1, 3, 5, &c. by constructing on AM (fig. 7.) an harmonic curve, with any number of nodes and loops. Divide the parts AF, FD, DE, EM, equally in C, O, P, B. CB will correspond to the pipe, and the ordinates to the curve GFHDLEN will express the excursions of the plates of air.

If the pipe gives its fundamental note, its length must be represented by CO, and the undulations in it will resemble the vibrations of part CO of a cord, whose length AD is equal to 2CO, and which has a node in F.

If the pipe is sounding its octave, it will be represented by CP, and its undulations will resemble the vibrations of a cord CP, whose length AE is $\frac{4}{3}$ of CP, having nodes at F and D, &c. &c.

We can now see the possibility of such undulations existing in a pipe as will be permanent, and produce all the variety of notes by a mere change in the manner of blowing, and why these notes are in the order of the natural numbers, precisely as we observe to happen in winding the trumpet or French horn. We have, *1st*, the fundamental expressed by 1; then the octave 2; then the 12th, 3; the double octave 4; then the third major of that octave 5, or 17th of the fundamental; then the octave of the 12th, or the 5th of this double octave, = 6. We then jump to the triple octave 8, without producing the intermediate sound corresponding to $\frac{1}{7}$th of the pipe. With much attention we can hit it; and it is a fact that a person void of musical ear stumbles on it as easily as on any other. But the musician, finding this sound begin with hum, and his ear being grated with it, perhaps thinks that he is mistaking his embouchure, and he slides into the octave. After the triple octave, we easily hit the sounds corresponding to $\frac{1}{9}$ and $\frac{1}{10}$, which are the 2d and 3d of this octave. The next note $\frac{1}{11}$ is sharper than a just 4th. We easily produce the note 12, which is a just 5th; 13 is a false 6th; 14 is a sound of no use in our music, but easily hit; 15 and 16 give the exact 7th and 8th of this octave.

Thus, as we ascend, we introduce more notes into every octave, till at last we can nearly complete a very high octave; but in order to do this with success, and tolerable readiness, we must take an instrument of a very low pitch, that we may be able nearly to fill up the steps of the octave in which our melody lies. Few players can make the French horn or trombone sound its real fundamental, and the octave is generally mistaken for it. The proof of this is, that most players can

give

give the 5th of the lowest note that they are able to produce; whereas the 5th of the real fundamental cannot be uttered. Therefore that lowest note is not the fundamental, but the octave to the fundamental.

Few performers can sound even this second octave on a short instrument, such as the ordinary military trumpet; and what they imagine to be the fundamental sound of this instrument is the double octave above it. This appears very strange; and it may be asked, how we know what is really the fundamental note of a trumpet? The answer to this is to be obtained only by demonstrating, on mechanical principles, what is the frequency of undulation corresponding to a given length of pipe. This is a proposition equally fundamental with its corresponding one in the theory of musical cords; but we have reserved it till now, because many readers would stop short at such an investigation, who are able to understand completely what we have now delivered concerning the music of the trumpet.

Suppose therefore a pipe shut at both ends, and that the whole weight of the contained air is concentrated in its middle point, the rest retaining its elasticity without inertia; or (which is a more accurate conception), let the middle point be conceived as extending its elasticity to the two extremities of the pipe, being repelled from each by a force inversely as the distance. Let the length of this pipe be L. This may also express the weight of the middle plate of air, which will always be proportional to the length of the pipe, because all is supposed to be concentrated there. Let E be the elasticity of the air. This must be measured by the pressure of the atmosphere, or by the weight of the column of mercury in the barometer. Perhaps the rationale of this will be better conceived by some readers by considering E as the height of a homogeneous atmosphere. Then it is plain that E is to L as the weight of this atmospheric column to the weight of the column of the same air which fills the pipe whose length is L. Then it is also plain that E is to L as the external pressure; and consequently, as the elasticity which supports that pressure is to the weight or inertia of the matter to be moved. Let this middle plate or diaphragm be withdrawn from its place of rest to the very small distance a. The elasticity or repulsion will be augmented on one side and diminished on the other; and the difference between them is the only force which impels the diaphragm toward the middle point, and causes it to vibrate, or produces the undulation. It is plain that the repulsion on one side is $\frac{\frac{1}{2}L}{\frac{1}{2}L-a}\times E$, or $\frac{L}{L-2a}E$ $\left(\text{for } \frac{1}{2}L-a:\frac{1}{2}L=E:\frac{\frac{1}{2}LE}{\frac{1}{2}L-a}\right)$, and the repulsion on the other side is $\frac{\frac{1}{2}L}{\frac{1}{2}L+a}\times E$, or $\frac{L}{L+2a}E$. The difference of these repulsions is $E\times L\times\frac{4a}{L^2-4a^2}$. But as we suppose a exceedingly small in comparison with L, this difference, or the accelerating force, may safely be expressed by $E\frac{4a}{L}$, or $4a\frac{E}{L}$.

Hence we deduce, in the first place, that the undulations will be isochronous, whether wide or narrow; because the accelerating force is always proportional to the distance a from the middle point.

Now, let a pendulum, whose quantity of matter is L, and length a, be supposed to vibrate in a cycloid by the force $\frac{4a}{L}E$, or $\frac{4E}{L}a$. It must perform its vibrations in the same time with the plate of air; because the moving force, the matter to be moved, and the space along which they are to be similarly impelled, are the same in both cases. Let another pendulum, having the same quantity of matter L, vibrate by its weight L alone. In order that these two pendulums may vibrate in equal times, their lengths must be as the accelerating forces. Therefore we must have $\frac{4E}{L}a:L=a:\frac{aL^2}{4Ea}, =\frac{L^2}{4E}$, which is therefore the length of the synchronous pendulum.

Now, a cord without weight and inertia, but loaded with the weight L at its middle point, and strained by a weight E, and drawn from the axis to the distance a, is precisely similar in its motion to the diaphragm we are now considering, and must make its oscillations in the same time.

This is applicable to any number of plates of air, by substituting in the cord a loaded point for each of the plates; for when the case is thus changed, both in the pipe and the cord, the space to be passed over by the plate of air bears the same proportion to a, which is passed over by the whole air concentrated in the middle point, which the space to be passed over by the corresponding loaded point of the cord bears to that passed over by the whole matter of the cord concentrated in the middle point; and the same equality of ratios obtains in the accelerating forces of the plate of air and the corresponding loaded point of the cord. Suppose, then, a pipe divided into 2, 3, 4, &c. equal parts, by 1, 2, 3, diaphragms, each of which contains the air of the intervening portion of the pipe, the whole weight L being equally divided among them. If there be but one diaphragm, its weight must be L; if two, the weight of each must be $\frac{1}{2}$ L; if three, the weight of each must be $\frac{1}{3}$ L; and so on for any number.

By considering this attentively, we may infer, without farther investigation, what will be the undulations of all the different plates of air in a pipe stopped at both ends. We have only to compare it with a cord similarly divided and loaded. Increase the number of loaded points, and diminish the load on each, continually—it is evident that this terminates in the case of a simple cord, with its matter uniformly diffused; and a simple pipe, with its air also uniformly diffused over its whole length.

Therefore, if we take an elastic cord, and stretch it by such a weight that the extending weight may bear the same proportion to the accelerating force acting on the whole matter concentrated in its middle point, which the elasticity of the air bears to its accelerating force acting on the whole matter concentrated at the mouth of an open pipe, sounding its fundamental note, the cord and the air will vibrate in the same time. Moreover, since the proportion between the vibrations of a cord so constituted, and those of a cord having its matter uniformly diffused, is the same with the proportion between the undulations in a pipe so constituted, and those of a pipe in which the air is uniformly diffused—it is plain that the vibrations of the cord and of the pipe

Musical Trumpet.

pipe in their natural state will also be performed in equal times.

We look on this as the easiest way of obtaining a distinct perception of the authority on which we rest our knowledge of the absolute number of undulations of the air in a pipe of given length. It may be obtained directly; and Daniel Bernoulli, Euler, and others, have given very elegant solutions of this problem, without having recourse to the analogy of the vibrations of cords and undulations of a column of air. But it requires more mathematical knowledge than many readers are possessed of who are fully able to follow out this analogical investigation.

Let us therefore compare this theory with experiment. What we call an open pipe of an organ is the same which we, in this theory, have considered as a pipe open at both ends; for the opening at the foot, which the organ-builders call the VOICE of the pipe, is equivalent to a complete opening. The aperture, and the sharp edge which divides the wind, may be continued all round, and the wind admitted by a circular slit, as is represented in fig. 10 We have tried this, and it gives the most brilliant and clear tones we ever heard, far exceeding the tones of the organ. An open organ pipe, therefore, when sounding its fundamental note, undulates with one node in its middle, and its undulations are analogous, in respect of their mechanism, with the vibrations of a wire of the same length, and the same weight, with the column of air in the pipe, and stretched by a weight equal to that of a column of the same air, reaching to the top of a homogeneous atmosphere, or equal to the weight of a column of mercury as high as that in the barometer

Dr Smith (see *Harmonics*, 2d edit. p. 193) found that a brass wire, whose length was 35,55 inches, and weight 31 troy grains, and stretched by 7 pounds avoirdupois, or 49000 grains, was in perfect unison with an open organ pipe whose length was 86,4 inches.

Now 86,4 inches of this wire weighs 75,34 grains. When the barometer stands at 30 inches, and the thermometer at 55° (the temperature at the time of the experiment), the height of a homogeneous atmosphere is 332640 inches. This has the same proportion to the length of the pipe which the pressure of the atmosphere has to the weight of the column of air contained in the pipe.

Now $86,4 : 332640 = 75,34 : 290060$. This wire, therefore, should be stretched (if the theory be just) by 290060 grains, in order to be unison with the other wire, and we should have $35,55^2 : 86,4^2 = 49000 : 290060$
But, in truth, - $35,55^2 : 86,4^2 = 49000 : 289430$
The difference is - - - - - - 630
The error scarcely exceeds $\frac{1}{500}$, and does not amount to an error of one vibration in a second.

We must therefore account this theory as accurate, seeing that it agrees with experiment with all desirable exactness.

We may also deduce from it a very compendious rule for determining the absolute number of aereal pulses made by an open pipe of any given length. When considering the vibrations of cords, we found that the number of vibrations made in a second is $\sqrt{\frac{386E}{LW}}$, where E is the extending weight, W the weight of the cord, and L its length. Let H be the height of a homogeneous atmosphere. We have its weight $= \frac{HW}{L}, = E$. Therefore substituting $\frac{HW}{L}$ for E in the above formula, we have the number of aereal pulses made per second $= \sqrt{\frac{386H}{L^2}}$, or $= \frac{\sqrt{386H}}{L}$. Now $\sqrt{386H}$, computed in inches, is 11331. Therefore, if we also measure the length of the pipe L in inches, the pulses in a second are $= \frac{11331}{L}$. Thus, in the case before us, $\frac{11331}{86,4} = 131,12$, or this pipe produces 131 pulses in a second. Dr Smith found by experiment that it produced 130,9, differing only about $\frac{1}{5}$th of a pulse.

We see that the pitch of a pipe depends on the height of the homogeneous atmosphere. This may vary by a change of temperature. When the air is warmer it expands, and the weight of the induced column is lessened, while it still carries the same pressure. Therefore the pitch must rise. Dr Smith found his organ a full quarter tone higher in summer than in winter. The effect of this is often felt in concerts of wind instruments with stringed instruments. The heat which sharpens the tone of the first flattens the last. The harpsichord soon gets out of tune with the horns and flutes.

Sir Isaac Newton, comparing the velocity of sound with the number of pulses made by a pipe of given length, observed that the length of a pulse was twice the length of the open pipe which produced it. Divide the space passed over in a second by the number of pulses, and we obtain the length of each pulse. Now it was found that a pipe of 21,9 inches produced 262 pulses. The velocity of sound (as computed by the theory on which our investigation of the undulations in pipes proceeds) is 960 feet. Now $\frac{960\times12}{262}=44$ inches very nearly, the half of which is 22, which hardly differs from 21,9. The difference of this theoretical velocity of sound, and its real velocity 1142 feet per second, remains still to be accounted for. We may just observe here, that when a pipe is measured, and its length called 21,9, we do really allow it too little. The voice hole is equivalent to a portion, not inconsiderable of its length, as appears very clearly from the experiments of Mr Lambert on a variable pitch pipe, and on the German flute, recorded in the Berlin Memoirs for 1775. He found it equivalent to $\frac{1}{6}$th; and this is sufficient for reconciling these measures of a pulse with the real velocity of sound.

The determination which we have given of the undulations of air in an organ pipe is indirect, and is but a sketch of the beautiful theory of Daniel Bernoulli, in which he states with accuracy the precise undulation of each plate of air, both in respect of position, density, velocity, and direction of its motion. It is a pleasure to observe how the different equations coincide with those which express the vibrations of an elastic cord. But this would have taken up much room, and would not have been suited to the information of many curious readers, who can easily follow the train of reasoning which we have employed.

Mr Bernoulli applies the same theory to the explanation

Musical Trumpet.

nation of the undulations in flutes, or instruments whose sounds are modified by holes in the sides of the pipe. But this is foreign to our purpose of explaining the music of the trumpet. We shall only observe, that a hole made in that part of a pipe where a node should form itself, in order to render practicable the undulations competent to a particular note, prevents its formation, and in its place we only get such undulations (and their corresponding sounds) as have a loop in that place. The intelligent reader will perceive that this single circumstance will explain almost every phenomenon of flutes with holes; and also the effects of holes in instruments with a reed voice, such as the hautboy or clarionette.

We now see that the sound or musical pitch of a pipe is inversely as its length, in the same manner as in strings. And we learn, by comparing them, that the sound of a trumpet has the same pitch with an open organ pipe of the same length. A French horn, 16 feet long, has the sound C *fa ut*, which is also the sound of an open flute-pipe of that length.

The TROMBONE, great trumpet, or SACKBUT, is an old instrument described by Mersennus and other authors of the last century. It has a part which slides (air-tight) within the other. By this contrivance the pitch can be altered by the performer as he plays. This is a great improvement when in good hands; because we can thus correct all the false notes of the trumpet, which are very offensive, when they occur in an emphatical or holding note of a piece of music. We can even employ this contrivance for filling up the blanks in the lower octaves.

We must not take leave of this subject without taking notice of another discovery of Mr Bernoulli's, which is exceedingly curious, and of the greatest importance in the philosophy of music.

Artists had long ago observed that the deep notes of musical instruments are sometimes accompanied by their harmonic sounds. This is most clearly perceived in bells, some of which give these harmonics, particularly the 12th, almost as strong as the fundamental. Musicians, by attending more carefully to the thing, seem now to think that this accompaniment is universal. If one of the finest sounding strings of the bases of a harpsichord be struck, we can hear the 12th very plainly as the sound is dying away, and the 17th major is the last sound that dies away on the ear. This will be rendered much more sensible, if we divide the wire into five parts, and at the points of division tie round it a thread with a fast knot, and cut the ends off very short. This makes the string false indeed by the unequal loading; but, by rendering those parts somewhat less moveable by this additional matter, the portions of the wire between these points are thus jogged, as it were, into secondary vibrations, which have a more sensible proportion to the fundamental vibration. This is still more sensible in the sound of the strings of a violincello when so loaded; but we must be careful not to load them too much, because this would so much retard the fundamental vibration, without retarding the secondary vibrations, that both cannot be maintained together. (*N. B.* This experiment always produces a beat in the sound).—Listening to a fine sounding flute pipe of the organ, we can also very often perceive the same thing. Mr Rameau, and most other theorists in music, now assert that this is the essence of a musical sound, and *necessarily* exists in all of them, distinguishing them from harsh noises. Rameau has made this the foundation of his system of music, asserting that the pleasure of harmony results from the successful imitation of this harmony of Nature, (see MUSIC, *Encycl.*). But a little logic should convince these theorists that they must be mistaken. If a note is musical because it has these accompaniments, and by this composition alone is a musical note, what are these harmonics? Are they musical notes? This is granted. Therefore they have the same composition; and a musical note must consist at once of every possible sound; yet we know that this would be a jarring noise. A little mathematics, too, or mechanics, would have convinced them. A simple vibration is surely a most possible thing, and therefore a simple sound. No, say the theorists; for though the vibration of the cord may be simple, it produces such undulations in the air as excite in us the perception of the harmonics. But this is a mere assertion, and leaves the question undecided. Is not a simple undulation of the air as possible as the simple vibration of a cord?

It is, however, a very curious thing, that almost all musical sounds really have this accompaniment of the octave, 12th, double octave, and 17th major; for these are the harmonics that we hear.

The jealousy of Leibnitz and of John Bernoulli, and their unfriendly thoughts respecting all the British mathematicians, made John Bernoulli do every thing in his power to lessen the value of Dr Taylor's investigation of the vibration of a musical cord. Taylor gave him a good opportunity. Perhaps a little vain of his investigation of this abstruse matter, he thought too much of it. He affirmed that the harmonic curve was the essential form of a string giving a musical note. This was denied, without knowing at first whether it was true or false. But as the analytic mathematics improved, it was at length found that there are an infinity of forms into which an elastic cord can be thrown, which are consistent both with isochronous vibrations, whether wide or narrow, and also with the condition of the whole cord becoming a straight line at once. Euler, D'Alembert, and De la Grange, have prosecuted this matter with great ingenuity, and it is one of the finest problems of the present day.

Daniel Bernoulli, of a very different cast of mind from his illustrious friends, admired both Newton and Taylor; and so far from wishing to eclipse Dr Taylor by the additions he had made to his theory, tried whether he could not extend Taylor's doctrine as far as the author had said. When he took a review of what he had done while explaining the partial vibrations of musical cords, he thought it very possible that while a cord is vibrating in three portions, with two nodes or points of rest, and sounding the 12th to its fundamental, it might at the same time be also vibrating as a simple cord, and sounding its fundamental note. It was possible, he thought, that the three portions might be vibrating between the four points with a triple frequency, while the two middle nodes were vibrating across the straight line between the two pins; and thus the vibrating cord might be a moveable axis, to which the rapid vibrations of the three parts might always be referred. This was very specious; and when a little more attentively considered, became more probable: for if the

Musical Trumpet.

the cord $ApBqCrD$ (fig. 8.) be vibrating as a 12th to its fundamental AD, the points B and C are in equilibrio. If therefore these two points be laid hold of by hooks, and be drawn aside to β and γ, while the string is yet vibrating, this should not hinder the vibrations. If the hooks be annihilated in an instant, the whole should vibrate between A and D; and this should be in a way very different from the simple vibration. The question now is, will the cord *continue* to vibrate with the loops $\beta s \gamma$, $\beta q \gamma$, &c. in the 900th part of a second (for instance), while the whole string vibrates from $A\beta\gamma D$ to $A\beta'\gamma'D$ in the 300th part of a second? or will it at once acquire the form of the simple harmonic curve? The case in which it is most likely to take the latter mode of vibration is when the points β and γ are let go at the instant that each portion of the string is in the middle of its vibration, and therefore forms the line $A\beta\gamma D$. But a moment's consideration will shew us that it cannot do this; for at that instant the point v, for instance, which had come from q, is moving outwards with a most rapid motion, and therefore will continue to go outward, while β and γ are approaching the axis. The point w, on the contrary, is at this moment approaching the axis with a motion equally rapid. They cannot therefore all come to the axis at once, and the vibration must differ greatly from a simple one. On the other hand, let it be supposed that both species of vibrations can be preserved, and that, at the moment of letting go the points β and γ, the cord has the form $Am\beta q\gamma nD$. Then, when β and γ have come to B and C, having made $\frac{1}{4}$ a vibration, the point m will be in the axis, having made a vibration downward, and a half vibration upwards. q, in like manner, is in the axis, having made a whole vibration upwards, and half a vibration downwards. n is like m. Thus the whole comes to the axis at once; and in such a manner, that if the points B and C were instantly stopped, the three portions would continue their partial vibrations without any new effort. The result of this compound vibration must be a compound pulse of air, which will excite in us the perception of the fundamental sound and of its 12th. The consequence will be the same if the points β and γ are stopped any where short of the axis; and therefore (said Bernoulli) the string will really vibrate so if not stopped at all.

But this was refused by Euler, who observed that in the points β and γ of contrary flexure, having no curvature, there can be no accelerating force. This caused Bernoulli to attempt a direct investigation, examining minutely the curvatures and accelerating forces in the different points.

He had the pleasure of finding that the accelerating forces arising from the curvature in every point, were precisely such as would produce the accelerations necessary in those points for performing the motion that was required. And he exhibited the equations expressive of the state of the cord in all these points. And, on the faith of these equations, he restored the Taylorean curve to the rank which its inventor had given it; and he asserted that in every musical vibration the cord was disposed in a harmonical curve either simple or compound. He farther shewed that the equations which Euler and D'Alembert had given for the musical cord (at least in the cases which they had published) were included in his equations, and that their equations only exhibited its momentary states, while his own equations shewed the physical connection of them all; which is, that the whole cord forms a harmonic curve between the two fixed pins, while its different portions form subordinate harmonic curves on the first as an axis. Euler and D'Alembert, although they acknowledge this in the particular cases which they had taken as examples, on account of their simplicity, still insist that no subordinate harmonic vibrations can correspond to all the states of an elastic cord which their equations exhibit as isochronous and permanent. Mr Bernoulli's death put an end to the controversy, and the question (considered as a general theory) is perhaps still undecided. It may very probably be true, that as a simple vibration may be permanent which never has the form of the simple harmonic described by Dr Taylor, so a vibration may exist compounded of such vibrations, and therefore not expressible by any equation deduced from the Taylorean curve.

But, in the mean time, Mr Bernoulli has made the most beautiful discovery in mechanics which has appeared in the course of the present century, and has explained the most curious phenomenon of continued sounds, *viz.* the *almost universal* accompaniment of the harmonic notes of any fundamental sound. For this *susceptibility* of compounded variation is not confined to a 12th, but is equally demonstrable of every other harmonic. Nay, it is evident that the same simple vibration of a cord may furnish a moveable axis to more than one harmonic. For as the simple vibration can have a subordinate harmonic vibration superinduced upon it, so may this compounded vibration have another superinduced on it, and so on to any degree of composition. And farther, as Mr Bernoulli has shewn the complete analogy between the accelerations of the different points of an elastic cord and of the corresponding plates of a column of air, it legitimately follows that all the consequences which we can easily deduce, respecting the vibrations of an elastic cord, may be affirmed respecting the undulations of a column of air in a pipe. Therefore this accompaniment of the harmonics must not be confined to the music of strings and bells, but equally obtains in the music of wind instruments. And thus the doctrine becomes universal.

Mr Bernoulli did not think it enough to shew that these compound vibrations are possible. He endeavours to shew that this accompaniment must be frequent. He illustrates this very prettily, by supposing that a toothed wheel is turned round, and rubs with its teeth on an elastic cord. If the successive dropping of the teeth keep exactly pace with such vibrations as the cord can take and maintain by its elasticity, these will certainly be formed on it. If the intervals do not *exactly* correspond, a little reflection will shew that the agitation which the cord acquires will approximate to those which it can maintain; and, if when they are exactly so in any place of it, and the wheel be in that instant removed, this vibration will remain and diffuse itself throught he rest of the cord; so that the very last dying quiver (so to speak) will be a harmonic. Every *harmonic* agitation tends, by the very nature of the thing, to continue, while those that are incompatible really *do* destroy each other; and the very last must be the remainder or superplus of such as could continue,

over those which destroyed each other. Accordingly, the harmonic notes of wires are always most distinctly heard as the sound is dying away.

There is no occasion now to say any thing about the fallacy of Rameau's *Generation Harmonique* as a theory of musical pleasure. Our harmonies please us, not because a sound is accompanied by its harmonics, but because harmonics please. His principle is therefore a tautology, and gives no instruction whatever. His theory is a very *forced* accommodation of this principle to the practice of musicians, and taste of the Public. He is exceedingly puzzled in the case of the *sousdominante*, or 4th of the scale, and the 6th where there is no resonance. He says that these notes, "fremissent, quoiqu' elles ne resonnent pas." But this misleads us. They do not resound; because a 4th and a 6th cannot be produced at all by dividing the cord. They tremble; because the false 4th and false 6th are very near the true ones, and the true 4th and 6th would both tremble and resound, if they were made false. A string will both tremble and resound, if very nearly true, as any one observes the 12th and 17th on a harpsichord tremble and resound very strongly, though they are tempered notes. The whole theory is overturned at once by tuning the 4th false, so as to correspond to an aliquot division of the cord. It will then resound; and it this had happened to be agreeable, it would have been catched at as the sousdominant.

The physical cause of the pleasure of harmonic sounds is yet to seek, as much as our choice of those notes for melody which give us the best harmony (see TEMPERAMENT, *Suppl.*). We have no hesitation in saying that, with respect to our choice, the two are quite independent. Thousands enjoy the highest pleasure from melody who never heard a harmonious sound. All the untaught singers, and all simple nations, are examples. They not only fix on certain intervals as the steps of their tunes, but are disgusted when other steps are taken. Nor do we hesitate, for the very same reasons, to say that the rules of accompaniment are dependent on the cantus or air, and by no means on the fundamental bass of Rameau. The dependence assumed by him, as the rule of accompaniment, would, if properly adhered to, according to his own notions of the comparative values of the harmonics, lead to the most fantastic airs imaginable, always jumping by large intervals, and altogether incompatible with graceful music. The rules of modulation which he has squeezed out of his principle, are nothing but forced, very forced, accommodations of a very vague principle to the current practice of his contemporaries. They do not suit the primitive melodies of many nations; and they have caused these national musics to degenerate. This is acknowledged by all who are not perverted by the prevailing habits. We have heard, and could write down, some most enchanting lullabies of simple peasant women, possessed of musical sensibility, but far removed, in the cool sequestered vale of life, from all opportunities of stealing from our great composers. Some of these lullabies never fail to charm, even the most erudite musician, when sung by a fine flexible voice: but it would puzzle Mr Rameau to accompany them *secundum artem*.

We conclude this subject by describing a most beautiful and instructive experiment.

Mr Watt, the celebrated engineer, was amusing himself (about the year 1765) with organ building, and invented a monochord of continued sound, by which he could tune an organ with mathematical precision, according to any proposed system of temperament. It consisted of a covered string of a violincello, sounding by the friction of an ivory wheel. The instrument did not answer Mr Watt's purpose, by reason of the dead harshness of its tone, and a flutter in the string by the unequal action of the wheel. But Mr Watt was amused by observing the string frequently taking, of its own accord, points of division, which remained fixed, while the rest was in a state of strong vibration. The instrument came into the possession of the writer of this article. He soon saw that it gave him an opportunity of making all the experiments which Bernoulli could only relate. When the string was kept in a state of simple vibration, by a very uniform and gentle motion of the wheel, if its middle point was then gently touched with a quill, this point immediately stopped, but the string continued to vibrate in two parts, sounding the octave: And this it continued to do, however strong the vibrations were rendered afterwards by increasing the pressure and velocity of the wheel. The same thing happened if the string was gently touched at one third. It instantly divided itself into three parts, with two nodes, and sounded the 12th. In the same manner the double octave, the 17th, and all other harmonics, were produced and maintained.

But the prettiest experiment was to put something soft, such as a lock of cotton, in the way of the wide vibrations of the cord, at one third and two-thirds of its length, so as to disturb them when they became very wide. When this was done, the string instantly put on the appearance of fig. 8. performing at once the full vibration competent to its whole length, and the three subordinate vibrations, corresponding to one-third of its length, and sounding the fundamental and the 12th with equal strength. In this manner all the different accompaniments were produced at pleasure, and could be continued, even with strong sounds. And it was amusing to observe, when the wheel was strongly pressed to the string, and the motion violent, the nodes would form themselves on various parts of the string, running from one part to another. This was always accompanied with all the jarring sounds which corresponded to them.

When the string was making very gentle, simple vibrations, and the wheel hardly touching it, if a violincello was made to sound the 12th very strongly in its neighbourhood, the string instantly divided itself, and vibrated in unison, frequently retaining its simple vibration and fundamental tone. We recommend this experiment to every person who wishes to make himself well acquainted with the mechanism of musical sounds. He will see, in a most sensible and convincing manner, how a single string of the Æolian harp gives us all the changes of harmony, sliding from one sound to another, according as it is affected in its different parts by an irregular breeze of wind. The writer of this article has attempted to regulate these sweet harmonic notes, and to introduce them into the organ. His success has been very encouraging, and the sounds far exceed in pathetic sweetness any that have yet been produced by that noble instrument. But he has not yet brought them fully under command, nor made them strong enough for any thing but the softest chamber music. Other

necessary occupations prevent him from giving the attention to this subject that it deserves. He recommends it therefore to the musical instrument makers as richly deserving their notice. His general method was this: A wooden pipe is made, whose section is a double square. A partition in the middle divides it into two pipes, along side of each other. One of them communicates with the foot and wind chest, and is shut at the upper end. The other is open at the upper, and shut at the lower end. In the partition there is a slit almost the whole length, and the sides of this slit are brought to a very smooth chamfered or feather edge. A fine catgut is strained in this slit, so as almost to touch the sides. It is evident that when the wind enters one pipe by the foot, it passes through the slit into the other, and escapes at the top, which is open. In its passage it forces the catgut into motion, and produces a musical note, having all the sweetness of the Æolian harp. The strength of sound may be increased by increasing the body of air which is made to undulate. This was done by using, instead of catgut, very narrow silk tape or ribband varnished: but the unavoidable raggedness of the edges made the sounds coarse and wheezing. Flat silver wire was not sufficiently elastic; flat wire, used for watch balance springs, was better, but still very weak sounded. Other methods were tried, which promised better. A thin round plate of metal, properly supported by a spring, was set in a round hole, made in another plate not so thin, so as just not to touch the sides. The air forced through this hole made the spring plate tremble, dancing in and out, and produced a very bold and mellow sound.—This, and similar experiments, are richly worth attention, and promise great additions to our instrumental music.

TSCHIRNHAUS (Ehrenfried Walther Von), a name well known in the republic of letters, and one of the ornaments of the last century, was born April 10. 1651, at Kislingswald near Gorlitz in Upper Lusatia. His father was Ernest Christopher Von Tschirnhaus, Baron Kislingswald and Stoltzberg, and Obernschonfeld, privy counsellor, and in various offices of rank under the Electors George I. and II. of Saxony, the first of whom honoured him with the distinction of the gold chain and portrait, as a mark of his sense of his merits and services. The mother of the young Von Tschirnhaus was Maria Stirling, daughter of *Baro a Stirling et Achil*, Stirling of Achil, or Achyle, in Scotland, an old and respectable family, as appears by an epitaph which the Duke Christian, brother of the Elector George II. inscribed on the tomb of Johan Albert Stirling of Achil, in the cathedral of Marckspurg. This gentleman had been president of the senate of the electorate, privy counsellor, director of the imposts, and master of horse to the Prince, and had, by his faithful and useful services, acquired his highest esteem.

E. W. Von Tschirnhaus was born, as has been observed, at Kislingswald, the usual residence of the family, and possessed by it during more than 300 years. The family came originally from Bohemia, and appears to have been considerable, seeing that, from the earliest accounts of it in Lusatia, the Barons of Kislingswald are generally found in the most respectable civil offices.

The figure which Baron Von Tschirnhaus, the subject of this relation, has made in the scientific and political world, makes it superfluous to say that his early years were well employed. Quick apprehension, a clear perception of the subject of his thoughts, and the most ardent and insatiable thirst for knowledge, distinguished him during his academical education. When 17 years of age, he was sent to Leyden. In 1672 all study was interrupted in Holland by the din of war; and Mr Von Tschirnhaus left the university for the camp. His knowledge in mathematics, mechanics, and all physical science, found ample room in the military service for shewing the importance of those sciences; and Tschirnhaus so distinguished himself by his service in this way, that Baron Nieuland, a general officer of great merit, and at the same time an accomplished scholar, took delight in pushing him into every service where he could shew himself and his talents.

Tschirnhaus.

After two years service, he returned to his father's; but finding little to interest him in the life of a mere country gentleman, and still burning with the same thirst of knowledge, he prevailed on his father to allow him to travel. His younger brother George Albrecht Von Tschirnhaus, Baron Oberschonfeld, which he inherited from his grandfather Stirling, loved him with the warmest affection, and supplied him liberally with what was required for his appearance everywhere in a manner becoming his rank, and for fully gratifying his curiosity. He used often to say, "Sorry was I to lose the company of my dear brother, and I sometimes wished to accompany him; but not having his thirst for knowledge, I knew that his love for me would debar him of much happiness, which I should thus have obstructed." *Felices animæ!* He went to Holland, from thence into England, France, Italy, Sicily, Malta, Greece.—Returning through the Tyrol, he met his brother at Vienna, where both were in great favour at the court of Leopold Wherever he went, he made himself acquainted with the most eminent in all departments of science, living with them all in the mutual exchange of discoveries and of kind offices. In Holland he was intimate with Huyghens and Hudde; in England, with Newton, Wallis, Hailey, and Oldenburgh; in France, among a people who more speedily contract acquaintance, there was not a man of note with whom he did not cultivate an active acquaintance—and, fortunately, Leibnitz then lived at Paris: in Italy, he was particular caressed by Michaeli, soon after Cardinal; and was in the closest correspondence with Kircher. His enjoyments, however, were derived solely from the communications of the most eminent; his curiosity was directed to every thing, and wherever he saw an ingenious artisan, he was eager to learn from him something useful. In 1682, when at Paris for the third time, he communicated to his friends his celebrated theory of the caustic curves, which marked him out as a valuable acquisition, and he was elected a member of the Royal Academy of Sciences, which was then reformed by the great minister Colbert, and the most illustrious in all nations were picked out for its ornaments. There he found himself seated with Leibnitz, Huyghens, John Bernoulli, &c.

After twelve years employed in visiting Europe, he returned home: but after a short stay, went to Flanders, and prepared to publish his work, intitled *Medicina Mentis*; of which the subject may almost be guessed, from the way in which he had exercised his own mind. Having the most exalted notions of the intellectual and moral

moral nature of man, he thought that the continual supply of information was as necessary as the continual supply of food. And his great principle was TO ENLIGHTEN. This work was committed to the care of some friends, and did not appear till 1687, at Amsterdam. A second edition appeared at Leipsic in 1695.

Finding now that his moderate fortune was insufficient for the great public projects he had in view, he sought for assistance, and endeavoured to make friends by frequenting the court of the Elector at Dresden. He soon became a favourite of his Princes, George the II. and III. and was appointed to active offices of great responsibility. By the orders and encouragement of the Elector, then king of Poland, he introduced into his native country the first manufacture of glass; and his project soon throve to such a degree, that not only Saxony was supplied, but they even began to export the finer kinds of white glass for windows; in which manufacture Saxony still excels. It was in the course of experiments for improving this manufacture that Tschirnhaus made the celebrated great burning glasses which still bear his name. He made two of these lenses, and gave one to the Emperor, and the other to the Academy of Paris. He was eager to improve the art of forming and polishing optical glasses; and in the prosecution of the theory on which their performance depends, he made some beautiful discoveries in the department of pure geometry. It is well known that all the sciences are allied, and of a family, and that eminence in one is seldom attainable without the assistance of others. His present pursuits led him to the study of chemistry, which he prosecuted with the same ardour which he exhibited in every thing he undertook. But all the while, mathematics, and especially geometry, was his favourite study; and he was anxious to make the same advances in the general paths of mathematical investigation which he thought he had made in the general laws of material nature. He apprehended that only bye paths were yet known, and that many things were yet inaccessible; because we had not yet found out the great roads from which those branches were derived. He was of Des Cartes's opinion, that the true road in mathematics must be an easy one, except in cases which were, in their own nature, complicated. Very early, therefore, he began writing on mathematical subjects, always continuing his general views of the science, and his endeavours to systematise the study; but, at the same time, bestowing a very particular attention on any branch which chanced to interest him; each of these his episodical studies in mathematics deserves the name of a department of the science. This is the case with his theory of caustic curves, with his method of tangents, and his attempt to free Leibnitz's calculus from all consideration of infinitesimal quantities. Mr Tschirnhaus seldom gave himself any trouble with a particular problem. In all his mathematical performances, there is an evident connection with something which he considered as the great whole of the science; and the manner of treating the different questions is plainly accommodated to a system in his thoughts. This he intended as the third part of the Medicina Mentis; and, having nearly completed the second, he had proposed these as the occupation of the ensuing winter (1708-9). But his death, which may be called premature, has deprived the world of these, and other beneficent and useful labours.

Tschirnhaus.

Mr Von Tschirnhaus was of the most mild and gentle disposition, as was well known to all who enjoyed his acquaintance. This disposition was so eminent in him, that scarcely any person ever saw him angry, or even much ruffled in his temper. He forgave injuries frankly and heartily, and often stood the friend (unknown) of those who had wronged him. By such conduct, he changed some enmities into the most steady and affectionate friendships. As an inquirer and an inventor, he had contentions with other claimants, and some disputes about the legitimacy of his methods; as, for example, with Nicholas Fatio Duiller, who attacked Tschirnhaus's method of tangents; and Prestet and Rolle, who found fault with his expression of equations of the third degree. But these were all friendly debates, and never carried him beyond the limits of gentlemanly behaviour. He began to dispute with Ozanam about a quadratrix; but on being merely told that he was mistaken, by P. Souciet, he immediately acknowledged his error, and corrected it.

Many original and important mathematical performances of Mr Von Tschirnhaus are to be seen in the Leipsic Acts, in the Memoirs of the Academy of Sciences at Paris, and other literary journals. His happy generalisation of Dr Barrow's theorem for the focus of a slender pencil of rays after reflection or refraction, and the theory of caustic curves, in which this terminates, both constitutes one of the most elegant branches of optical science, and affords a rich harvest of very curious and unexpected geometrical truths. The manner in which he notices the rough way in which his first and sole mistake in this theory was pointed out, is perhaps incomparable as an example of gentlemanlike reprehension, and is a lesson for literati of all descriptions, highly valuable on account of the soft way in which it falls, while it is convincing as a mathematical theorem.

Tschirnhaus was the discoverer of the substance of which the celebrated Saxon porcelain is made, and of the manner of working it up; by which he established a manufacture highly profitable to his country, and has given us the finest pottery in the world. He never wearied in spreading useful knowledge; and the shops of our artisans of almost all kinds were supplied with books of instructions and patterns, many of them written by Mr Von Tschirnhaus, or under his inspection. Useful books of all kinds were translated out of foreign languages at his expence. Men of genius in the arts were enabled, through the encouragement of himself and his friends, and often by his pecuniary assistance, to bring their talents before the public eye. In short, he seemed at all times to prefer the public good to his own; and never felt so much pleasure as when he could promote science or the useful arts. He was as it were stimulated to this by an innate propensity. And as he was more desirous of *being* than of *appearing* the accomplished man, he was in no concern what notice others took of his services to the public. He even represents the desire of fame as hostile to the improvement either of science or morality, in his *Medicina Mentis*; a work which is acknowledged by all who knew him to be a picture of his own amiable mind. He lightly esteemed riches; and knew not what

use

Tschirnhaus. use they were of, except for providing the necessaries of life, and the means of acquiring knowledge. In perfect conformity to this maxim, he modestly, and with elegant respect, refused the ample presents made him by his affectionate sovereign; and when he was added to his cabinet council, he received the diploma, but begged and obtained to be free from the title. And when he presented his great burning glass to the Emperor, and got from him the dignity and insignia of Baron of the Empire, he pleaded for leave to decline it, requesting to keep the chain and portrait, which he always wore under his vest. He expended a very great portion of the ample revenue left him by his father in the service of his country, by promoting the useful arts and sciences.

Mr Von Tschirnhaus venerated truth above all things; saying, that those who thought any thing comparable with it were not the sons of God. but step-children, and that the love of truth is the ruling affection in every man of a worthy heart. In a letter to an intimate friend, he said that, by the age of five-and-twenty, he had completely subdued the love of glory, of riches, and of worldly pleasures; and that at no time he had found it difficult to repress vanity, because he was every day conscious of having acted worse than he was certain that he might and should have done. He felt himself humbled in the sight of the All perfect Judge.

Nor was all this the vain boast of a man averse to business, and possessed of an ample fortune, which permitted him, without inconvenience, to please his fancy in study, and in helping others with what to himself was superfluous. Such a character, though rare, may exist, without being the object of much respect. No: Mr Tschirnhaus was really a philosopher of the true stoic sect, in respect of fortitude of mind, while a good Christian in modesty and diffidence. In the last five years of his life he bore up under troubles, and embarrassments, and misfortunes in his family, which would have tried the mind of Cato himself. But in the midst of these storms he was unshaken, and preserved his serenity of mind. He was even sensible of this being a rare gift of Providence, and used frequently to express his thankfulness for a treasure so precious. He felt deeply his relation to the Author of Nature, and rejoiced in thinking himself subject to the providence of God. He said that he was fully persuaded that he would meet with perfect justice, and would therefore strive to perform his own part to the utmost of his power, that his future condition might be the more happy, and that he might in the mean time enjoy more satisfaction on reflecting on his own conduct. His lot, he said, was peculiarly fortunate: having such thirst for novelty, he would have been unhappy without an affluent fortune; and his own enjoyments encouraged neither vice nor idleness in himself or in the ministers to his pleasures.

This amiable person was of a constitution not puny, but not robust, and he had hurt it by too constant study. He feared no disease; thinking that he had a cure or an alleviation for all but one, namely, the stone and gravel. He had a dread of this, and laboured to find a preventative or a remedy. He thought that he had also done a great deal here; and describes in his *Medicina Corporis* a preparation of whey, which he said he used with great advantage to his health. But his precautions were in vain: He was attacked with the gravel, which, after three months suffering, brought on a suppression of urine. The physicians saw that his end approached; and finding him disregard their prescriptions, they quitted him. He treated himself (it is said judiciously) for some time, and with some appearance of success; but at last he saw death not far off. He dictated a letter to his Sovereign, thanking him for all his favours and kindness, and recommended his children to his protection. He never fretted nor complained; but frequently, with glistening eyes, expressed his warmest thanks to Providence for the wonderful track of good fortune and of happiness that he had enjoyed; and said that he also felt some satisfaction in the consciousness that some of this was owing to his own prudent conduct. He possessed his entire faculties to the last moment; and when he felt his spirit just about to depart, his last words were, "*Jö triumphe—Victoria!*" No longer able to speak, he made signs for what he wanted; and a little after, shutting his eyes, as if to sleep, he gently, and without a groan, yielded up his spirit, about four o'clock in the morning of the 11th of October 1708, aged 56.

His funeral was performed in a manner becoming his rank, and the body conveyed to the family vault. The Elector (King of Poland) defrayed the expence; for he would not allow his family to have any thing to do with the funeral of a man of so public a character, and so universally beloved.

The account of such a life as that of Baron Von Tschirnhaus would, at all times, make a pleasant and useful impression. In these our times, in the end of the 18th century, after society has availed itself of all the acquisitions in science and art, furnished by that ardent age of the world which this gentleman contributed to adorn; in an age when we boast of illumination unparalleled in history, and of improvements almost amounting to perfection; and in particular, of an emancipation from the prejudices which had obscured our view of the chief good, and stifled public spirit—now, when we are so full of knowledge that it is running over on all hands, in volumes of instruction, how to make the world one happy family; in these bright days of philanthropism, can the public records of Europe exhibit a superior character to that of Mr Von Tschirnhaus, either in respect of wisdom or of disposition? Was he not a philanthropist, a sincere lover of mankind? Was he not wise, in employing his great acquired knowledge as the means of direct and active beneficence, by limiting his exertions to the extent of those circles where his own efforts would be effective? He did not write books, teaching others how to do good: he taught it by example; being determined that his own wishes to see men happier should not fail by the want of such wishes in others, even after he should instruct them. He never allowed his insatiable curiosity for fresh discoveries to interfere with the immediate turning to the good of his own country the knowledge he had already acquired. He probably never thought of improving the situation of the Chinese or the Mexicans, finding that it required all his ample fortune, and all the interest and influence he could acquire, to do the good he wished in Saxony. We doubt not but that he was equally attentive to the still

still narrower circle of duties formed by his own family. We see that he was a dearly beloved brother; which could hardly be without his also being a loving brother and a dutiful son. The nature of the distresses which he experienced in his family, and the manner in which he behaved under them, shew him to have been an eminent Christian moralist. With a modesty that is unmatched by any one of the thousands who have poured out instructions upon us during the last ten years, and a gracefulness which characterises the gentleman, his *Medicina Mentis* is offered to public notice, merely as an experimental proof that a certain way of thinking and acting is productive of internal quiet of mind; of great mental enjoyment, both moral and intellectual; and of peace, and the good will of those around us: and that it did, in fact, produce a dutiful and comfortable resignation to the unavoidable trials of human life. He pretends not to be greatly superior in wisdom to his neighbours, but merely tells how things succeeded with himself. He did not scruple, however, to publish to the world discoveries in science, in which he had got the start of others during that busy period of scientific occupation: and these discoveries in mathematics were highly prized by the first men of the age; nor will the name of Tschirnhaus, or his caustic curves, ever be forgotten.

We felt ourselves obliged to the friend who took notice of the omission of this gentleman's name, so eminent in the mathematical world, in the course of our alphabet; but when we looked into the Memoirs of the Academy of Paris for 1709 for some account of him, what we there saw appeared such a continual panegyric, that we could not take it as a fair picture of any real character. Looking about for more impartial information, we found in the *Acta Eruditorum*, Leipf. 1709, the account of which the foregoing is an abstract, except a particular or two which we have copied from an account in the Literary Journal of Breslaw, by Count Herberstein, whom we can scarcely suspect of undue partiality, because he had some disputes with Mr Von Tschirnhaus on mathematical subjects. May we not say, "the memory of this man is sweet!"

TSHAMIE, the Indian name of a tree in the Northern Circars of Hindostan. It grows, says Dr Roxburgh, to be a pretty large tree, is a native of most parts of the coast, chiefly of low lands at a considerable distance from the sea, and may be only a variety of *prosopis spicigera*, for the thorns are in this sometimes wanting; flowers during the cold and beginning of the hot seasons. *Trunk* tolerably erect, bark deeply cracked, dirty ash colour. *Branches* irregular, very numerous, forming a pretty large shady head. *Prickles* scattered over the small branches; in some trees wanting. *Leaves* alternate, generally bipinnate, from two to three inches long; pinnæ from one to four, when in pairs opposite, and have a gland between their insertions. *Leaflets* opposite, from seven to ten pair, obliquely lanced, smooth, entire, about half an inch long, and one-sixth broad. *Stipules* none. *Spikes* several, axillary, filiform, nearly erect. *Bracts* minute, one-flowered, falling. *Flowers* numerous, small, yellow, single, approximated. *Calyx* below, five-toothed. *Filaments* united at the base. *Anthers* incumbent, a white gland on the apex of each, which falls off soon after the flower expands. *Style* crooked. *Stigma* simple. *Legume* long, pendulous, not inflated. *Seeds* many, lodged in a brown meally substance.

The pod of this tree is the only part used. It is about an inch in circumference, and from six to twelve long; when ripe, brown, smooth, and contains, besides the seeds, a large quantity of a brown meally substance, which the natives eat; its taste is sweetish and agreeable; it may therefore be compared to the Spanish *algaroba*, or locust tree. (*Ceratonia siliqua*, Linn.)

In compliance with Dr Kœnig's opinion, Dr Roxburgh calls this tree a *prosopis*; but as he thinks the antheral glands give it a claim to the genus *adenanthera*, we have retained the Indian name till its botanical classification shall be ascertained by those who have greater authority in the science than we lay claim to.

TUCKER (Abraham), Esq; a curious and original thinker, was a gentleman of affluent fortune, and author of "The Light of Nature pursued," 9 vols 8vo; of which the five first volumes were published by himself in 1768, under the assumed name of "Edward Search, Esq;" and the four last after his death, in 1775, as "The posthumous Work of Abraham Tucker, Esq; published from his manuscript as intended for the press by the author." Mr Tucker lived at Betchworth-castle, near Dorking, in Surrey; an estate which he purchased in the early part of his life. He married the daughter of Edward Barker, Esq; by whom he had two daughters; one of whom married Sir Henry St John, and died in his lifetime; the other survived, and now lives at Betchworth-castle. He lost his eyesight a few years before his death, which happened in 1775. To describe him as a neighbour, landlord, father, and magistrate, it would be necessary to mention the most amiable qualities in each. It is unnecessary to add, that he was very sincerely regretted by all who had the pleasure of his acquaintance, and who stood connected with him in any of those relations.

Tucker (Josiah, D. D.), well known as a political and commercial writer, was born at Langhorn, in Caermarthenshire, in the year 1712. His father was a farmer, and having a small estate left him at or near Aberystwith, in Cardiganshire, he removed thither; and perceiving that his son had a turn for learning, he sent him to Ruthin school, in Denbighshire, where he made so respectable a progress in the classics, that he obtained an exhibition at Jesus College, Oxford. It is generally understood that several of his journeys to and from Oxford were performed on foot, with a stick on his shoulder, and bundle at the end of it. Thus it might be said by him, as by Simonides, "*Omnia mea mecum porto.*"

At the age of 23 he entered into holy orders, and served a curacy for some time in Gloucestershire. About 1737 he became curate of St Stephen's church in Bristol, and was appointed minor-canon in the cathedral of that city. Here he attracted the notice of Dr Joseph Butler, then Bishop of Bristol, and afterwards of Durham, who appointed Mr Tucker his domestic chaplain. By the interest of this prelate Mr Tucker obtained a probendal stall in the cathedral of Bristol; and on the death of Mr Catcott, well known by his treatise on the Deluge, and a volume of excellent sermons, he became rector of St Stephen. The inhabitants of that parish

confist chiefly of merchants and tradefmen: a circumftance which greatly aided his natural inclination for commercial and political ftudies.

When the famous bill was brought into the Houfe of Commons for the naturalization of the Jews, Mr Tucker, confidering the meafure rather as a merchant or politician than as a Chriftian divine, wrote in defence of it with a degree of zeal which, to fay no more, was at leaft indecent in a man of his profeffion. As fuch it was viewed by his brethren of the clergy, and by his parifhioners; for, while the former attacked him in pamphlets, newfpapers, and magazines, the latter burnt his effigy dreffed in canonicals, together with the letters which he had written in defence of the naturalization.

In the year 1753 he publifhed an able pamphlet on the "Turkey Trade;" in which he demonftrates the evils that refult to trade in general from chartered companies. At this period Lord Clare (afterward Earl Nugent) was returned to Parliament for Briftol; which honour he obtained chiefly through the ftrenuous exertions of Mr Tucker, whofe influence in his large and wealthy parifh was almoft decifive on fuch an occafion. In return for this favour, the Earl procured for him the deanery of Gloucefter, in 1758, at which time he took his degree of doctor in divinity. So great was his reputation for commercial knowledge, that Dr Thomas Hayter, afterwards Bifhop of London, who was then tutor to his prefent majefty, applied to Dr Tucker to draw up a differtation on this fubject for the perufal of his royal pupil. It was accordingly done, and gave great fatisfaction. This work, under the title of "The Elements of Commerce," was printed in quarto, but never publifhed.

Dr Warburton, who became Bifhop of Gloucefter in the year 1760, thinking very differently from Dr Tucker of the proper ftudies of a clergyman, as well as of the project for naturalizing the Jews, faid once to a perfon who was praifing the Elements of Commerce, that "his Dean's trade was religion, and religion his trade." This farcafm, though not perhaps groundlefs, was certainly too fevere; for fome of the Dean's publications evince him to have devoted part of his time at leaft to the ftudy of theology, and to have been a man of genuine benevolence.

In the year 1771, when a ftrong attempt was made to procure an abolition of fubfcription to the 39 articles, Dr Tucker came forward as an able and moderate advocate of the church of England. About this time he publifhed "Directions for Travellers;" in which he lays down excellent rules, by which gentlemen who vifit foreign countries may not only improve their own minds, but turn their obfervations to the benefit of their native country.

The Dean was an attentive obferver of the American conteft. He examined the affair with a very different eye from that of a party man, or an interefted merchant; and he difcovered, as he conceived, that both fides would be better off by an abfolute feparation. Mr Burke's language in the Houfe of Commons, in confequence of his publifhing this opinion, was harfh, if not illiberal. In his famous fpeech on the American taxation bill, April the 13th, 1774, he called the Dean of Gloucefter the advocate of the court faction, though it is well known that the court difapproved of the propofal as much as the oppofition. This attack roufed the Dean to refentment; and he publifhed a letter to Mr Burke; in which he not only vindicates the purity of his own principles, but retorts upon his adverfary in very forcible and farcaftic terms. He afterwards fupported Lord Nugent's intereft in Briftol againft that of Mr Burke, and was certainly very inftrumental in making the latter lofe his election.

When the terrors of an invafion were very prevalent in 1779, Dr Tucker circulated, in a variety of periodical publications, fome of the moft fenfible obfervations that were ever made on the fubject, in order to quiet the fears of the people. In 1781 he publifhed, what he had printed long before, "A Treatife on Civil Government," in which his principal defign is to counteract the doctrines of Locke and his followers. The book made a confiderable noife, and was very fharply attacked by feveral writers on the democratic fide of the queftion, particularly by Dr Towers and Dr Dunbar of Aberdeen. This laft gentleman acted a part which, if not difhonourable, was at leaft uncommon. The Dean had thrown off thirty copies of his work long before he publifhed it; and thefe he fent to different men of eminence, that he might avail himfelf of their animadverfions before he fhould fubmit it to the public at large. Principal Campbell of Aberdeen received one copy for this purpofe; and Dr Dunbar having by him been favoured with a perufal of it, inftead of fending his objections privately to the author, publifhed fevere remarks on it in a work which he had then in the prefs. Thus was the anfwer to the Dean of Gloucefter's Treatife on Government publifhed before that treatife itfelf; but Dr Dunbar was no match for Dr Tucker.

In the year 1782 our author clofed his political career with a pamphlet intitled "*Cui Bono?*" in which he balances the profit and lofs of each of the belligerent powers, and recapitulates all his former pofitions on the fubject of war and colonial poffeffions. His publications fince that period confifted of fome tracts on the commercial regulations of Ireland, on the exportation of woollens, and on the iron trade. In 1777 he publifhed feventeen practical fermons, in one volume octavo. In the year 1778, one of his parifhioners, Mifs Pelloquin, a maiden lady of large fortune and moft exemplary piety, bequeathed to the Dean her dwelling-houfe in Queen Square, Briftol, with a very handfome legacy, as a teftimony of her great efteem for his worth and talents. In the year 1781 the Dean married a lady of the name of Crowe, who refided at Gloucefter.

It fhould be recorded to his praife, that though enjoying but very moderate preferment (for to a man of no paternal eftate, or other ecclefiaftical dignity, the Deanery of Gloucefter is no very advantageous fituation), he was notwithftanding a liberal benefactor to feveral public inftitutions, and a diftinguifhed patron of merit. The celebrated John Henderfon of Pembroke-college, Oxford, was fent to the univerfity, and fupported there, at the Dean's expence, when he had no means whatever of gratifying his ardent defire for ftudy. We fhall mention another inftance of generofity in this place, which reflects the greateft honour upon the Dean. About the year 1790 he thought of refigning his rectory in Briftol, and, without communicating his defign to any other perfon, he applied to the Chancellor, in whofe

Tucker. Tulipomania.

whose gift it is, for leave to quit it in favour of his curate, a most deserving man, with a large family. His Lordship was willing enough that he should give up the living, but he refused him the liberty of nominating his successor. On this the Dean resolved to hold the living himself till he could find a fit opportunity to succeed in his object. After weighing the matter more deliberately, he communicated his wish to his parishioners, and advised them to draw up a petition to the Chancellor in favour of the curate. This was accordingly done, and signed by all of them, without any exception, either on the part of the dissenters or others. The Chancellor being touched with this testimony of love between a clergyman and his people, yielded at last to the application; in consequence of which the Dean cheerfully resigned the living to a successor well qualified to tread in his steps. Since that time he resided chiefly at Gloucester, viewing his approaching dissolution with the placid mind of a Christian, conscious of having done his duty both to God and man. He died in November 1799. The following we believe to be a tolerably correct list of his works.

Theological and Controversial.—1. A Sermon, preached before the Governors of the Infirmary of Bristol, 1745. 2. Letters in behalf of the Naturalization of the Jews. 3. Apology for the Church of England, 1772. 4. Six Sermons, 12mo, 1773. 5. Letter to Dr Kippis on his Vindication of the Protestant Dissenting Ministers. 6. Two Sermons and Four Tracts. 7. View of the Difficulties of the Trinitarian, Arian, and Socinian Systems, and Seventeen Sermons, 1777.

Political and Commercial.—8. A pamphlet on the Turkey Trade. 9. A brief View of the Advantages and Disadvantages which attend a Trade with France. 10. Reflections on the Expediency of Naturalizing foreign Protestants, and a Letter to a Friend on the same Subject. 11. The Pleas and Arguments of the Mother Country and the Colonies stated. 12. A Letter to Mr Burke. 13. Quere, Whether a Connection with, or Separation from, America, would be for national Advantage? 14. Answers to Objections against the Separation from America. 15. A Treatise on Civil Government. 16. *Cui Bono?* 17. Four Letters on national Subjects. 18. Sequel to Sir William Jones on Government. 19. On the Dispute between Great Britain and Ireland. 20. Several Papers under the Signature of Cassandra, &c. on the Difficulties attendant on an Invasion. 21. A Treatise on Commerce (Mr Coxe, in his Life of Sir Robert Walpole, says that this was printed, but never published.)

Miscellaneous.—22. Directions for Travellers. 23. Cautions against the Use of Spirituous Liquors. 24. A Tract against the Diversions of Cock-fighting, &c.

TULIPOMANIA, the very proper name given to a kind of gambling traffic in *tulip-roots*, which prevailed in Holland and the Netherlands during some part of the 17th century. It was carried on to the greatest extent in Amsterdam, Haerlem, Utrecht, Alkmaar, Leyden, Rotterdam, Hoorn, Enkhuysen, and Meedenblick; and rose to the greatest height in the years 163[illegible], 1635, 1636, and 1637. Munting, who, in 16[illegible]6, wrote a book of [illegible]000 pages folio on the subject, has given a few of the most extravagant prices, of which we shall present the reader with the following. For a root of that species called the *Viceroy*, the after-mentioned articles, valued as below, were agreed to be delivered.

	Florins.
2 lasts of wheat	448
4 ditto rye	558
4 fat oxen	480
8 fat swine	240
12 fat sheep	120
2 hogsheads of wine	70
4 tons beer	32
2 ditto butter	192
1000 pounds of cheese	120
a complete bed	100
a suit of clothes	80
a silver beaker	60
Sum	2500

These tulips afterwards were sold according to the weight of the roots. Four hundred perits* of Admiral Liefken cost 4400 florins; 446 ditto of Admiral Von der Eyk, 1620 florins; 106 perits Schilder cost 1615 florins; 200 ditto Semper Augustus, 5500 florins; 410 ditto Viceroy, 3000 florins, &c. The species Semper Augustus has been often sold for 2000 florins; and it once happened that there were only two roots of it to be had, the one at Amsterdam and the other at Haerlem. For a root of this species, one agreed to give 4600 florins, together with a new carriage, two grey horses, and a complete harness. Another agreed to give twelve acres of land for a root: for those who had not ready money, promised their moveable and immoveable goods, house and lands, cattle and clothes. A man, whose name Munting once knew, but could not recollect, won by this trade more than 60,000 florins in the course of four months. It was followed not only by mercantile people, but also by the first noblemen, citizens of every description, mechanics, seamen, farmers, turf-diggers, chimney-sweeps, footmen, maid-servants, and old clothes women, &c. At first, every one won and no one lost. Some of the poorest people gained in a few months houses, coaches, and horses, and figured away like the first characters in the land. In every town some tavern was selected which served as a change, where high and low traded in flowers, and confirmed their bargains with the most sumptuous entertainments. They formed laws for themselves, and had their notaries and clerks.

* A *perit* is a small weight less than a grain.

To get possession of fine flowers was by no means the real object of this trade, though many have said that it was, and though we have known some individuals in Scotland, who, led away by what they thought the fashion, have given ten guineas for a tulip root. During the time of the tulipomania, a speculator often offered and paid large sums for a root which he never received, and never wished to receive. Another sold roots which he never possessed or delivered. Oft did a nobleman purchase of a chimney-sweep tulips to the amount of 2000 florins, and sold them at the same time to a farmer; and neither the nobleman, chimney-sweep, or farmer, had roots in their possession, or wished to possess them. Before the tulip season was over, more roots were sold and purchased, bespoke, and promised to be delivered, than in all probability were to be found in the gardens of Holland; and when Semper Augustus was

Tulipomania.

was not to be had, which happened twice, no species perhaps was oftener purchased and sold. In the space of three years, as Munting tells us, more than ten millions were expended in this trade in only one town of Holland.

To understand this gambling traffic, it may be necessary to make the following supposition. A nobleman bespoke of a merchant a tulip root, to be delivered in six months, at the price of 1000 florins. During these six months the price of that species of tulip must have risen or fallen, or remained as it was. We shall suppose that, at the expiration of that time, the price was 1500 florins; in that case, the nobleman did not wish to have the tulip, and the merchant paid him 500 florins, which the latter lost and the former won. If the price was fallen when the six months were expired, so that a root could be purchased for 800 florins, the nobleman then paid to the merchant 200 florins, which he received as so much gain; but if the price continued the same, that is, 1000 florins, neither party gained or lost. In all these circumstances, however, no one ever thought of delivering the roots or of receiving them. Henry Munting, in 1636, sold to a merchant at Alkmaar, a tulip root for 7000 florins, to be delivered in six months; but as the price during that time had fallen, the merchant paid, according to agreement, only 10 *per cent.* "So that my father (says the son) received 700 florins for nothing; but he would much rather have delivered the root itself for 7000." The term of these contracts was often much shorter, and on that account the trade became brisker. In proportion as more gained by this traffic, more engaged in it; and those who had money to pay to one, had soon money to receive of another; as at faro, one loses upon one card, and at the same time wins on another. The tulip dealers often discounted sums also, and transferred their debts to one another; so that large sums were paid without cash, without bills, and without goods, as by the Virements at Lyons. The whole of this trade was a game at hazard, as the Mississippi trade was afterwards, and as stock jobbing is at present. The only difference between the tulip trade and stock-jobbing is, that at the end of the contract the price in the latter is determined by the Stock Exchange; whereas in the former it was determined by that at which most bargains were made. High and low priced kinds of tulips were procured, in order that both the rich and the poor might gamble with them; and the roots were weighed by perits, that an imagined whole might be divided, and that people might not only have whole, but half and quarter lots. Whoever is surprised that such a traffic should become general, needs only to reflect upon what is done where lotteries are established, by which trades are often neglected, and even abandoned, because a speedier mode of getting fortunes is pointed out to the lower classes.

At length, however, this trade fell all of a sudden. Among such a number of contracts many were broken; many had engaged to pay more than they were able; the whole stock of the adventurers was consumed by the extravagance of the winners; new adventurers no more engaged in it; and many becoming sensible of the odious traffic in which they had been concerned, returned to their former occupations. By these means, as the value of tulips still fell, and never rose, the sellers wished to deliver the roots *in natura* to the purchasers at the prices agreed on; but as the latter had no desire for tulips at even such a low rate, they refused to take them or to pay for them. To end this dispute, the tulip-dealers of Alkmaar sent, in the year 1637, deputies to Amsterdam; and a resolution was passed on the 24th of February, that all contracts made prior to the last of November 1636 should be null and void; and that, in those made after that date, purchasers should be free on paying ten *per cent.* to the vender.

The more disgusted people became with this trade, the more did complaints increase to the magistrates of the different towns; but as the courts there would take no cognizance of it, the complainants applied to the States of Holland and West Friesland. These referred the business to the determination of the provincial council at the Hague; which, on the 27th of April 1637, declared that it would not deliver its opinion on this traffic until it had received more information on the subject; that in the mean time every vender should offer his tulips to the purchaser; and, in case he refused to receive them, the vender should either keep them, or sell them to another, and have recourse on the purchaser for any loss he might sustain. It was ordered also, that all contracts should remain in force till farther enquiry was made. But as no one could foresee what judgment would be given respecting the validity of each contract, the buyers were more obstinate in refusing payment than before; and venders, thinking it much safer to accommodate matters amicably, were at length satisfied with a small profit instead of exorbitant gain: and thus ended this extraordinary traffic, or rather gambling. *Beckmann's History of Inventions*, vol. i.

Tulipomania || Turnsol.

TUMAR, in Bengal, rent-roll or assessment.

TUMBREL, is a kind of carriage with two wheels, used either in husbandry for dung, or in artillery to carry the tools of the pioneers, &c. and sometimes likewise the money of an army.

TUNGSTEN (see CHEMISTRY, n° 178, &c. in this *Suppl.*) when well fused, is, according to Guyton *alias* Morveau, of no higher specific gravity than 8.3406. This is very different from the specific gravity which has hitherto been assigned to it. The same eminent chemist concludes, from its extreme brittleness and difficulty of fusion, that it affords little promise of utility in the arts, except in metallic alloys, or by virtue of the property which its oxyd possesses, of affording fixed colours, or giving fixity to the colours of vegetables.

TURNSOL, a dye-stuff manufactured in Holland, the preparation of which was long kept a profound secret. In order to mislead foreigners, the Dutch pretended that turnsol was made from rags dyed with the juice of the sun-flower (*Helianthus*), from which it obtained its name. Since the late revolution, however, in Holland, the true method employed by the Dutch for preparing this colour has been discovered, and the process is as follows:—That kind of lichen called orchil (LICHEN-*Rocella*. See that article in this *Suppl.*), or, when that cannot be procured, the large oak-moss, after being dried and cleaned, is reduced to powder, and by means of a kind of oil-press the powder is forced thro' a brass sieve, the holes of which are small. The sifted powder is then thrown into a trough and mixed with an alkali called *vetas*, which is nothing else than the ashes

ashes of wine lees, in the proportion of half a pound of ashes to one pound of powder. This mixture is moistened with a little human urine, for that of other animals contains less ammonia, by which a fermentation is produced; and the moistness is still kept up by the addition of more urine. As soon as the mixture assumes a red colour, it is poured into another trough; is again moistened with urine, and than stirred round in order that the fermentation may be renewed. In the course of a few days it acquires a bluish colour, and is then carefully mixed with a third part of very pure pulverised potash; after which the mixture is put into wooden pails, three feet in height, and about half a foot broad. When the third fermentation takes place, and the paste has acquired a considerably dark blue colour, it is mixed with chalk or pulverised marble, and stirred well round that the whole may be completely united. This last substance gives the colour no higher quality, and is intended merely to add to the weight. The blue, prepared in this manner, is poured into oblong square iron moulds; and the cakes, when formed, are placed upon fir boards on an airy floor in order to dry, after which they are packed up for sale.

TURPENTINE, a well known substance extracted from the pine. Under the article PINUS (*Encycl.*), we have given an account of one process by which this extract is made; but the following, which is taken from the 31st volume of the *Journal de Physique*, is very different, and probably better. The pine from which turpentine is extracted, is never fit for this operation till it be thirty years of age. The extraction is begun in February and continued to the end of October. Incisions are made with an hatchet, beginning at the foot of the tree on one side, and rising successively: they are repeated once or twice a week, the size about one finger's breadth across, and three or four inches long. During the four years in which it is continued, the incisions have risen to about eight or nine feet. Then the incisions are begun on the other side; and during this time the old ones fill up, and may be again opened after some years, so that a tree on a good soil, and well managed, may yield turpentine for a century. At the bottom of the tree, under the incision, a hole is dug in the ground to receive the resin which flows from the tree. This resin is called *terebinthine brut*, is of a milky colour, and is that which flows during the three summer months; it requires further purification.

The winter crop is called *barras galipot*, or white resin: it sticks to the bark of the tree, when the heat has not been strong enough to let it flow into the trough in the ground. It is scraped off with iron knives.

Two methods are practised for purifying these resins. That which is followed at Bayonne is to have a copper cauldron which will hold 300lb. of materials fixed over a fire, and the flame circulating at the bottom of the copper. The turpentine is put in, melted with a gentle heat, and, when liquid, it is strained through a straw-basket made for the purpose, and stretched over a barrel, which receives the strained turpentine. This purification gives it a golden colour, and may be performed at all times of the year.

The second manner, which is practised only in the mountain of De Buch, near Bourdeaux, consists in having a large tub, seven or eight feet square, and pierced with small holes at the bottom, set upon another tub to catch the liquor. This is exposed to the hottest sun for the whole day, filled two thirds with turpentine, which as it melts falls through the holes, and leaves the impurities behind. This pure turpentine is less golden-coloured, and is much more esteemed than the other. This process can only be done in the summer.

To make *oil* of turpentine, an alembic, with a worm like what is used by the distillers, is employed here. It generally contains 250lb. of turpentine, which is boiled gently, and kept at the boiling point till no more oil passes, when the fire is damped This generally gives 60lb. of oil, and the operation lasts one day

The boiling turpentine, when it will give no more oil, is tapped off from the still and flows into a tub, and from thence into a mold of sand, which it fills, and is suffered to cool for at least two days without disturbing it. This residue is known under the name of *colo fone*. It is of a brown colour, and very dry. It may be made clearer and nearer in colour to that of the rosin, by adding hot water to it before it is tapped off the still, and still boiling and stirring the water well with it, which is done with a besom of wet straw; and it is then sold for rosin, but is little esteemed, as it contains no essential oil.

TUSCULANUM, a villa belonging to Cicero, near Tusculum, where he wrote his *Quæstiones Tusculanæ*, so named from the place; thus become famous as well for the productions of genius as of nature. Formerly the villa of Sylla: now called *Grotta Ferrata*.—Another *Tusculanum* (inscription), a town of the Transpadana, situated on the west side of the Lacus Benacus. Now said to be called *Toscolaro*, in the territory of Brescia, subject to Venice. Here many monuments of antiquity are dug up.

TUSCULUM (anc. geog.), a town of Latium, to the north of Alba; situated on an eminence, and therefore called *Supernum* (Horace, Strabo). In sight of Rome, at about the distance of 100 stadia, or 12 miles. Adorned with plantations and princely edifices: the spot remarkable for the goodness of the soil, and its plenty of water. Built by Telegonus, who slew his father Ulysses (Ovid, Horace); called the grandson of Ulysses in Silius Italicus. A municipium (Cicero); the birth-place of the elder Cato (Nepos, Cicero). Now *Frescati*, in the Campania of Rome.

TUTENAG, according to Sir George Staunton, is, properly speaking, zinc extracted from a rich ore, or calamine. The ore is powdered and mixed with charcoal-dust, and placed in earthen jars over a slow fire, by means of which the metal rises in the form of vapour, in a common distilling apparatus, and afterwards is condensed in water. The calamine from which tutenag is thus extracted, contains very little iron, and no lead or arsenic, so common in the calamine of Europe (See CALAMINE, *Encycl.*) Hence it is that tutenag is more beautiful than our zinc, and that the white copper of the Chinese takes so fine a polish. See *White Copper*, in this *Supplement*.

TYERS (Thomas), an author both in poetry and prose, the friend of Johnson, and well known to most of the eminent characters of the present time, was a student of the Temple in 1753. His father intended him for the law, but the young man it seems penned a sonnet when he should engross. He was an accomplished, but not a profound man; and had taste and ele-

Typography.

gance of mind, ſlightly tinged with gleams of genius. He wrote ſome paſtorals and political tracts, which probably will not ſurvive the partiality of his particular friends.

TYPOGRAPHY, as the word imports, is the art of printing by types; but it is likewiſe uſed to ſignify the multiplying of copies by any mechanical contrivance. Of the art of printing by types, and the many improvements from time to time either made or attempted in it, a pretty full account will be found in the *Encyclopædia*, under the titles LETTER, LOGOGRAPHY, and PRINTING; and in this *Supplement* under the word PRINTING. Of typography, in the other and larger ſenſe, ſome account may likewiſe be found in the *Encyclopædia* under the title *Method of Copying* WRITINGS; but to almoſt all theſe articles there is ample room for ſome additions here.

The *ſtereotype* printing of *Didot* and *Herhan*, being conſidered in France as a great improvement, muſt not be paſſed over wholly without notice. The term *ſtereotype* is derived from the Greek words στερεος and τυπος, becauſe in this method the types are fixed and immoveable in the form, ſo that none of them can be pulled or diſplaced by the preſſman. We need hardly obſerve, to thoſe who are at all acquainted with the hiſtory of printing, that the project of ſoldering a whole form together, or of caſting a ſolid form from an impreſſion made by a general ſyſtem of types, or page ready compoſed, is not new. It was realiſed 70 years ago by WILLIAM GED, a goldſmith in Edinburgh; for an account of whoſe method we refer the reader to his life in the *Encyclopædia*. Didot now follows nearly the ſame proceſs as Ged. He does not indeed caſt his types in a maſs, but after the form is compoſed and carefully corrected, he cements or ſolders the types together ſo firmly that none of them is liable to be looſened by the action of the preſs or the adheſion of the balls. How far this method of printing is of value with regard to books which are altered and improved in every ſubſequent edition, may, perhaps, be queſtioned; but on a looſe conſideration of the ſubject, it ſeems as if it would, in every caſe, be advantageous to a bookſeller to print a few copies of a work, and keep the types ſtanding to print others as they may be wanted;—we ſay it would be advantageous, if it were not for the immenſe value in types, which would, by that means, be locked up. To form ſome judgment of this, it may be ſtated, that the works of Virgil, printed by Didot, in 18mo, form a beautiful volume of 418 pages, of 35 lines each. The character ranges line for line with that called burgeois, N° 2. in Caſlon's book of ſpecimens, the face of the letter being rather ſmaller; and we are told * that the price of the plates of this work is twelve hundred franks, or 50l. ſterling. From this fact ſome judgment may be formed of the commercial queſtion. We have caſually looked at different books printed by Didot, but can ſay nothing of their correctneſs: the page is very pretty.

* *La Decade Philoſophique.*

For multiplying copies of any writing, or of a book of ordinary ſize, Rochon, of the French National Inſtitute, and now Director of the Marine Obſervatory at the port of Breſt, invented, about the year 1781, a machine for engraving, with great celerity and correctneſs, the pages of the book or manuſcript on ſo many plates of copper. It was ſubmitted to the examination of a committee of the Royal Academy of Sciences, whoſe report of its utility was given in the following words:

"This machine appears to us to unite ſeveral advantages. 1*ſt*, Engraved editions of books may be executed, by this means, ſuperior to thoſe which can be made by the hand of the engraver, however ſkilful; and theſe engraved originals will be made with much more ſpeed, and much leſs expence. 2*d*, As this machine is portable, and of no conſiderable bulk, it may become very uſeful in armies, fleets, and public offices, for the impreſſion of orders, inſtructions, &c. 3*d*, It poſſeſſes the advantage which, in a variety of circumſtances, is highly valuable, of being capable of being uſed by any man of intelligence and ſkill, without requiring the aſſiſtance of any profeſſional workman. And, *laſtly*, It affords the facility of waiting for the entire compoſition and engravings of a work before any of the copies are pulled off; the expence of plates, even for a work of conſiderable magnitude, being an object of little charge; and this liberty it affords to authors, may prove highly beneficial in works of which the chief merit conſiſts in the order, method, and connection of ideas."

Rochon's machine conſiſts of two braſs wheels *, placed on the ſame axis above each other, and ſeparated by a number of pillars, each two inches in length. Theſe two wheels, with the interval which ſeparates them, are equivalent to a ſingle wheel about three inches thick. In order therefore to ſimplify the deſcription, they are conſidered as a ſingle wheel which moves freely on its axis.

* See Plate XLVI.

This wheel is perforated near its circumference with a number of ſquare holes, which are the ſheaths or ſockets through which a like number of ſteel punches, of the ſame ſhape, are inſerted, and are capable of moving up and down. They are very well fitted; and from this circumſtance, as well as the thickneſs of the double wheel, they have no ſhake, or ſide motion, independent of the motion of the wheel itſelf. Every punch is urged upwards by a ſeparate ſpring, in ſuch a manner, that the wheel armed with its characters, or ſteel types (the lower faces of the punches being cut into the figures of the ſeveral letters), may turn freely on its axis; and if it be moved, the ſeveral punches will paſs in ſucceſſion beneath an upright ſcrew, for preſſure. The ſcrew is fixed in a very firm and ſolid frame, attached to the ſupports of the machine; and by this arrangement a copperplate, diſpoſed on the table, or bed of the apparatus, will receive the impreſſion of all the punches in ſucceſſion, as they may be brought beneath the vertical preſſing ſcrew, and ſubjected to its action.

But as the preſs is fixed, it would neceſſarily follow that each ſucceſſive impreſſion would, in part, deſtroy or mutilate the previous impreſſions, unleſs the plate itſelf were moveable. It therefore becomes neceſſary that the plate ſhould be moveable in two directions: the firſt, to determine the interval between the letters and words, and form the lines; and the other motion, which is more ſimple, becauſe its quantity may remain the ſame through the whole of a book, ſerves to give the interval between line and line, and to form the pages.

It will eaſily be conceived that it would be a tedious operation to ſeek, upon the circumference of the wheel, each ſeveral character, as it might be required to come beneath

beneath the press, because it is necessary to repeat this operation as many times as there are characters in a work. The author has considerably diminished the time and trouble of this operation, by fixing upon the axis of the great wheel, which carries the punches, another small wheel, about four inches in diameter, the teeth of which act upon a rack, which carries a rule moving between two sliders. This rule, or straight line, will therefore represent the developement, or unfolding of the circumference of the wheel which causes it to move, and will shew the position of the great wheel, which carries the punches. For these two wheels being concentric, the developement of the small toothed wheel, of about two inches radius, will exhibit, in a small space (for example, that of a foot), an accurate register of the relative positions of the punches with regard to the pressing-screw. To obtain this effect, nothing more is necessary than to place a fixed index opposite to the moveable rule, which last is divided in the following manner:

The punch on which the first letter of the alphabet is engraved, must be brought under the centre of the pressing-screw; and a line of division then drawn upon the moveable rule, to which the letter itself must be added to distinguish it. The index, already mentioned, being placed opposite, and upon this first division, will serve to place immediately beneath the pressing-screw the punch, or rather the character, corresponding with the division upon the rule, without its being afterwards necessary to inspect the place either of the punch or the screw, with regard to each other. Consequently, as soon as the divisions which correspond with all the punches inserted in the wheel are engraved upon the straight rule, the fixed index will immediately determine the position into which that wheel must be brought, in order to place the punches under the pressing-screw in the order which the work may require.

This register, for this name distinguishes the rule and its index, has no other function in the machine than to guide the hand of the operator, and to shew when the punch is very near its proper position beneath the pressing-screw. When this is the case, the required position is accurately obtained by means of a detent or catch.

The detent which he uses for this operation is a lever with two tails, one of which is urged toward the circumference of the wheel by a spring. To this extremity of the lever is fixed a piece of hardened steel, of the figure of a wedge, which, by means of a spring, is pressed towards the axis of the great wheel, but may be relieved, or drawn back, by pressure on the opposite tail of the lever, so as to permit the great wheel to revolve at liberty.

In the next place, it must be explained how this detent takes hold of the wheel, so as to retain it precisely in the situation necessary to cause any one of the punches, at pleasure, to give its impression to the plate. For this purpose there are a number of notches cut in the circumference of the wheel, for the purpose of receiving the detent. These notches may be about half an inch deep, wider towards the circumference than elsewhere, and it will be of advantage that this outer width should be as great as the circumference of the wheel can conveniently allow. By this contrivance, the wedge will not fail to present itself opposite to one of the notches into which it will fall, and draw the wheel exactly to its due situation, even though the index of the register should not be brought precisely to the line of division appropriated to any particular letter. For if this last degree of precision were required in working the machine, it would be very prejudicial to the requisite speed which, above all things, is required in its use. When the wedge is therefore left at liberty, it not only enters immediately into its place, and moves the wheel till its two sides apply fairly to the interior surfaces of the notch, but retains the wheel in this state with the necessary degree of stability.

The method of giving the proper figure to these notches is very easy. For this purpose it is necessary, in the first place, to impress all the characters contained in the wheel on a plate of copper or pewter. The support on which the plate is fixed must be moved in a right line, after each stroke of the punch, through such a space that the characters may be arranged one after the other without touching. Now, as the perfect linear arrangement (supposing every other part to be true) must depend on the notches, it might seem sufficient to cut these according to the method used for the wheels of clock-work: but as it is very difficult to avoid some obliquity on the face of the punch, and perhaps in the hole through which it passes, it is in almost every case necessary to retouch the notch itself. The requisite degree of precision may be easily obtained, when, upon examining with attention the print of the characters engraved upon the plate, the inequalities shall have been ascertained by a very fine line passing exactly under the base of two similar letters, assumed as objects of comparison: for the irregularity of linear position may, by this means, be determined with great exactness, and remedied to the most extreme nicety. In this operation, the workman must file away part of that surface of the notch which is opposite to the direction of the motion the character requires. Great care must be taken to file only a small portion at a time, in order that the instant may be seized at which the wedge, by entering into the notch, brings the character to its due situation.

These details, respecting the right-lined arrangement on the characters, must not divert our attention from the very great celerity with which any letter is brought to its place under the press by means of the register and detent. This celerity is an object of so much importance in the engraving of a great work, that every means ought to be pursued which may tend to increase it. For this reason it is, that instead of following the alphabetic order in the arrangement of punches on the surface of the wheel, we ought to prefer that in which the sum of the different motions to be given to the wheel, for engraving an entire work, shall be the least possible. This tedious enquiry may well be dispensed with, by observing the order in which printers dispose their cases of characters, that the letters of the most frequent recurrence may be most immediately under the hand of the workman.

If all the characters afforded an equal resistance to impression in a plate of metal, a constant force would never fail to drive the punches to the same depth. But the faces of the letters are very unequal, and consequently it will be necessary to use a variable force. Most workmen use the hammer, and not a screw, as in this

this machine, for stamping. If the hammer had been used in this machine, it is evident, that if we supposed it to have fallen from the same height upon every one of the punches, the force of the stroke could be rendered variable according to the nature of the characters, by placing a capital, or head, upon each, of an height properly adjusted to receive the hammer after passing through a greater or less space. But the heads of our punches are variable at pleasure, because they are screwed on; and thus it is that, by experimentally adjusting the heads of all the punches, a set of impressions are obtained of equal depths from every one of them. When, for example, the letter *i* is placed under the hammer, the upper part of its head is at a small distance from the head of the hammer, in order that its fall, which begins always at the same place, may strike this letter weakly; but when the letter M is brought under the hammer, the upper part of its head being much less elevated than that of the letter *i*, will receive a much stronger blow. The impressions of the letters M and *i* will therefore always be equally deep, if the heads of the punches be once properly fixed by experiment.

Instead of the stroke of a hammer, however, our author makes use of the pressure of a screw, of which the threads are so inclined that it runs through its female socket, and would fall out merely by its own weight. This construction affords the double advantage of preserving the impressions from the effects of the circular motion, and of affording a fall in the screw of nearly nine lines for each revolution. The head of this screw is solidly fixed in the centre of a brass wheel, of which the position is horizontal. The diameter of this wheel must be sufficiently large, that its motion may not be perceptibly affected by the irregularities of friction in the screw. This considerable diameter is also requisite, because the pressure of the screw depends, not only upon the force which is applied, but the distance of the place of application from the centre of movement.

It is essential that this wheel should have very little shake; for which reason it is advisable that the axis of the screw should be prolonged above the wheel itself, that it may slide in a socket firmly fixed to the frame of the machine. In this situation, the wheel, which is fixed on the prolongation of the screw, will have its plane constantly preserved in a situation parallel to itself, without any libration, notwithstanding the rise and fall of near nine lines, or three quarters of an inch, which it undergoes for each revolution on its axis.

It has been stated, as a requisite condition, that the screw should constantly fall from the same fixed point, or elevation, upon the heads of every one of the punches. To accomplish this essential purpose, a lever is firmly fixed to the support of the screw; which lever resembles the beam of a balance, having one of its extremities armed with a claw, and the other serving to give it motion through a small vertical space. The claw falls into a notch in the upper surface of the wheel attached to the screw, as soon as that wheel has risen to the desired elevation; and the lever itself is so far limited in its motion, that it cannot take hold of the wheel, excepting when it has reached that height. The wheel, therefore, remains confined and immoveable, by means of this detent, and cannot descend until it is delivered by pressure upon the opposite tail of the lever. In this machine, the wheel which has the pressing screw for its axis does not perform an entire revolution. It was with a view that there might never be any fall capable of shaking and disturbing the machine that the author determined to use only two-thirds of a revolution to strike those punches, which afford the strongest resistance. The screw consequently falls only through six lines upon those heads which are least elevated, and about two lines upon those which stand highest. Whence the difference between the extreme heights does not exceed four lines.

It is obvious, that so small a difference is not sufficient to strike all the characters from M to the letter *i*, when the wheel which governs the screw is put in motion by a constant weight, of which the impulse, like that of a hammer, is increased only by the acceleration of its fall. It is evident that this requisite variation of force might be had by changing the weight; but it is equally clear, that the numberless and incessant changes which the engraving of an entire work would demand, would be incompatible with that degree of speed which forms one of the first requisites. He was therefore obliged to render the force of the weight, which turns the screw, variable, by causing it to act upon levers of greater or less lengths, according to the different quantities of impulse required by the several punches. For this purpose he adopted the following construction: He connected by a steel chain to the wheel, which moves the screw, another wheel, having its axis horizontal, so that the two wheels respectively command each other. They are of equal diameter, and the chain is no longer than to make an entire turn round each wheel. This second wheel, or leading pulley, is intended to afford the requisite variations of force, which it does by means of a snail fixed upon its axis. The snail is acted upon by a cord passing over its spiral circumference, or groove, and bearing a weight which is only to be changed when a new set of punches for characters of a different size are put into the great wheel. The spiral is so formed, that when the weight descends only through a small space, the part of the cord, which is unwound, acts at a very short distance from the centre of the pulley; but when the fall is greater, the part of the snail upon which it acts is so far enlarged as to afford a much longer lever, and, consequently, to give a proportionally greater effect to the stroke. This construction, therefore, by giving the advantage of a longer lever to a greater fall of the screw, affords all the power which the nature of the work, and the different spaces of the letters demand.

The support on which the plate is fixed must, as has before been remarked, move so as to form strait lines. This motion, which serves to space the different characters with precision, is obtained by means of a screw, the axis of which remains fixed, and carries a female screw or nut. The nut itself is attached to the support of the metallic plate, which receives the letters, and carries it in the right lined direction without any deviation; because it is confined in a groove formed between two pieces of metal. The screw is moved by a lever, which can turn it in one direction only, because it acts by a click upon a ratchet-wheel, which is fixed to the head of the screw. The action of this lever always begins from a fixed stop; but the space through which it moves is variable, according to the respective breadths of the letters. This new consideration induced M. Rochon to fix upon the rule or plate of the register, a number

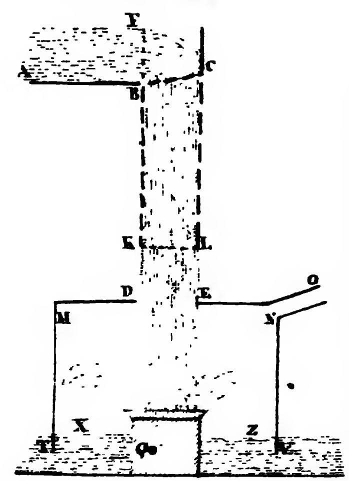
WATER BLOWING



Typography || Tyrtæus.

number of pins, correfponding with the different divifions which anfwer to each punch: thefe pins determine the diftance to which the lever can move. It therefore becomes a condition, that its pofition in the machine fhould be oppofite to the fixed index which determines the character at any time beneath the preffing-fcrew. The lever and its pin are therefore the fole agents employed to fpace the characters. If the plate were not moved by the lever, the impreffions would fall upon each other; and thus, for example, the letter *i* would be totally obliterated by the impreffion of the letter *l*.

Whenever, therefore, it is required to difpofe the letters *i* and *l* befide each other, the plate muft be moved after ftriking the letter *i* through a fpace equal to the quantity of the defired operation. Suppofe this to be one-fourth of a line, and that the lever fhould run through an arc of ten degrees to move the plate thro' this quantity; as foon as the pin of the letter *l* fhall be adjufted to the neceffary length to enable the lever to defcribe an arc of ten degrees, the operation of fpacing the two letters *i* and *l* will be reduced to that of placing the laft letter beneath the fixed index, and moving the plate till the lever fhall be ftopped by the pin belonging to the letter *l*. All the other letters will be equally fpaced, if the difpofition of the punches in the wheel be fuch, that the laft ftroke of any letter fhall confound itfelf with any letter of a fingle ftroke, fuppofing them to be impreffed one after the other, without moving the lever between ftroke and ftroke. This arrangement deferves to be very ferioufly attended to, becaufe the procefs could not be performed without it.

Many well-informed perfons are of opinion, that the perfect equality which this machine for engraving affords in the formation of letters and figns the moft difficult to be imitated, may afford a means of remedying the dangers of forgery. It is certain that the performance exhibits a fimple and ftriking character of precifion, which is fuch, that the leaft experienced eyes might flatter themfelves, in certain cafes, to diftinguifh counterfeits from originals. Lavoifier, whom the friends of fcience and the arts will not ceafe to regret, made fome experiments of this kind for the *caiffe de'fcompte*, which were attended with perfect fuccefs. Artifts appointed for that purpofe endeavoured in vain to imitate a vignette, formed by the fucceffive and equal motion of a character of ornament.

TYRTÆUS, an Athenian general and mufician, is celebrated by all antiquity for the compofition of military fongs and airs, as well as the performance of them. He was called to the affiftance of the Lacedæmonians in the fecond war with the Meffenians, about 685 B. C.; and a memorable victory which they obtained over that people is attributed by the ancient fcholiafts upon Horace to the animating found of a new military flute or clarion, invented and played upon by Tyrtæus. Plutarch tells us that they gave him the freedom of their city; and that his military airs were conftantly fung and played in the Spartan army to the laft hour of the republic. And Lycurgus the orator, in his oration againft Leocrates, fays, "The Spartans made a law, that whenever they were in arms, and going out upon any military expedition, they fhould all be firft fummoned to the king's tent to hear the fongs of Tyrtæus;" thinking it the beft means of fending them forth in a difpofition to die with pleafure for their country. Fragments of his poetry, in elegiac verfe, are preferved in Stobæus, Lycurgus Orat. in Fulvius Urfinus, at the end of Poems by illuftrious Women; and in the Oxford edition of *Eleg. & Lyric. Frag. & Scholia.* printed 1759. [illegible], &c.

Tyler.

TYTLER (William, Efq;), fo well known in the literary world as one of the ableft, and certainly the moft gentlemanly, of the defenders of the fame of Mary Queen of Scots, was born at Edinburgh, October 12. 1711. He was the fon of Mr Alexander Tytler, writer (or attorney) in Edinburgh, by Jane, daughter of Mr William Leflie, merchant in Aberdeen, and grand-daughter of Sir Patrick Leflie of Idan, provoft of that city. He received his education at the grammar fchool (or, as it is there called, the High School) and the univerfity of his native city, and diftinguifhed himfelf by an early proficiency in thofe claffical ftudies, which, to the lateft period of his life, were the occupation of his leifure hours, and a principal fource of his mental enjoyments.

In the year 1731, he attended the academical lectures of Mr Alexander Bayne, Profeffor of municipal law in the univerfity of Edinburgh, a gentleman diftinguifhed alike for his profeffional knowledge, his literary accomplifhments, and the elegance of his tafte. The Profeffor found in his pupil a congenial fpirit: and their connection, notwithftanding the difparity of their years, was foon ripened into all the intimacy of the ftricteft friendfhip. So ftrong indeed became at length that tie of affection, that the worthy Profeffor, in his latter years, not only made him the companion of his ftudies, but when at length the victim of a lingering difeafe, chofe him as the comforter of thofe many painful and melancholy hours which preceded his death.

At the age of 31, Mr Tytler was admitted into the Society of Writers to his Majefty's Signet, and continued the practice of that profeffion with very good fuccefs, and with equal refpect from his clients and the public, till his death, which happened on the 12th of September 1792. He married, in September 1745, Anne Craig, daughter of Mr James Craig of Dalnair, writer to the fignet, by whom he has left two fons, Alexander Frafer Tytler, his Majefty's Judge advocate for Scotland, and Profeffor of civil hiftory in the univerfity of Edinburgh; and Patrick Tytler, Lieutenant colonel of a regiment of fencible infantry, and Fort major of the caftle of Stirling; together with one daughter, Mifs Chriftina Tytler. His wife died about nine years before him; and, previoufly to that period, he had loft a fon and a daughter, both grown to maturity.

The moft remarkable feature of Mr Tytler's character was an ardour and activity of mind, prompted always by a ftrong fenfe of rectitude and honour. He felt with equal warmth the love of virtue and the hatred of vice; he was not apt to difguife either feeling, nor to compromife, as fome men more complying with the world might have done, with the fafhion of the time, or the difpofition of thofe around him. He feldom waved an argument on any topic of hiftory, of politics, or literature; he never retreated from one on any fubject that touched thofe more important points on which he had formed a decided opinion. Decided opinions he always formed on fubjects of importance; for on fuch fubjects he formed no opinions rafhly; and what he firmly believed he avowed with confidence, and fometimes with warmth.

Nor was it in opinion or argument only that this warmth and ardour of mind were confpicuous. They prompted him equally in action and conduct. His affection to his family, his attachment to his friends and companions, his compaffion for the unfortunate, were alike warm and active. He was in fentiment alfo what Johnfon (who felt it ftrongly in himfelf, and mentions it as the encomium of one of his friends) calls a *good hater*; but his hatred or refentment went no further than opinion or words, his better affections only rofe into action. In his opinions, or in his expreffion of them, there was fometimes a vehemence, an appearance of acrimony, which his friends might regret, and which ftrangers might cenfure; but he had no afperity in his mind to influence his actual conduct in life. He indulged oppofition, not enmity; and the world was juft to him in return. He had opponents; but two of his biographers, who knew him well, as well as the people with whom he moft affociated, declare their belief that he had not a fingle enemy. His contefts were on opinions, not on things; his difputes were hiftorical and literary. In converfation, he carried on thefe with uncommon intereft and vivacity; and the fame kind of impulfe which prompted his converfation (as is juftly obferved by an author, who publifhed fome notices of his life and character in the periodical work intitled *The Bee*) induced him to become an author. He wrote not from vanity or vain glory, which Rouffeau holds to be the only inducement to writing; he wrote to open his mind upon paper; to fpeak to the public thofe opinions which he had often fpoken in private; opinions on the truth of which he had firmly made up his own conviction, and was fometimes furprifed when he could not convince others: it was fair to try, if, by a fuller expofition of his arguments, he could convince the world.

With this view, he publifhed, in 1759, his "Inquiry, hiftorical and critical, into the Evidence againft *Mary Queen of Scots*, and an Examination of the Hiftories of Dr Robertfon and Mr Hume with refpect to that Evidence;" in which he warmly efpoufed the caufe of that unfortunate Princefs, attacked with feverity the conduct of her enemies, and expofed the fallacy, in many parts the fabrication, of thofe proofs on which the charges againft her had been founded.

This was a caufe worthy of an advocate who loved truth better than popular applaufe; and Mr Tytler evinced himfelf to be fuch an advocate. The problem of Mary's guilt or innocence, if confidered merely as a detached hiftorical fact, would appear an object which, at this diftance of time, feems hardly to merit that laborious and earneft inveftigation to which it has given rife; though, even in this point of view, the mind is naturally ftimulated to fearch out the truth of a dark myfterious event, difgraceful to human nature; and our feelings of juftice and moral rectitude are interefted to fix the guilt upon its true authors. But when we confider that this queftion involves a difcuffion of the politics of both England and Scotland during one of the moft interefting periods of their hiftory, and touches the characters, not only of the two fovereigns, but of their minifters and ftatefmen, it muft then be regarded in the light of a moft important hiftorical inquiry, without which our knowledge of the hiftory of our own country muft be obfcure, confufed, and unfatisfactory. In addition to thefe motives of inquiry, this queftion has exercifed fome of the ableft heads both of earlier and of latter times; and it is no mean pleafure to engage in a conteft of genius and of talents, and to try our ftrength in the decifion of a controverfy which has been maintained on both fides with confummate ability.

As we have elfewhere (fee Mary, *Encycl.*) given an abftract of the arguments on both fides of this difputed queftion, it would be altogether improper to repeat them here; but juftice to the fubject of this memoir requires us to fay, that by his manner of difcuffing it he acquired high reputation in the republic of letters. Before the appearance of the Inquiry, fays an ingenious writer, it was the fafhion for literary difputants to attack each other like mifcreants and banditti. The *perfon* was never feparated from the *caufe*; and whatever attached the *one*, was confidered as equally affecting the *other*; fo that fcurrility and abufe bloated the pages even of a Bentley and a Ruddiman. The Hiftorical Inquiry was free from every thing of that fort: and though the higheft name produced not a mitigation of the force of any argument, the meaneft never fuffered the fmalleft abufe. He confidered it as being greatly beneath the dignity of a man contending for truth, to overftretch even an argument in the fmalleft degree, far more to pervert a fact to anfwer his purpofe, on any occafion. In the courfe of his argument, he had too often occafion to fhew that this had been done by others; but he difdained to imitate them. His reafoning was forcible and elegant; impartially fevere, but always polite, and becoming the gentleman and the fcholar.

When this book appeared, it was univerfally read in Britain, and very well tranflated into French, under the title of "Recherches Hiftoriques et Critiques fur les Principales Preuves d l'Accufation intentée contre Marie Reine d'Ecoffe." The intereft it excited among literary men may be judged of from the character of thofe by whom it was reviewed on its publication, in the periodical works of the time. Dr Douglas, now bifhop of Salifbury, Dr Samuel Johnfon, Dr John Campbell, and Dr Smollet—all wrote reviews of Mr Tytler's book, containing very particular accounts of its merits, and elaborate analyfes of the chain of its arguments. As an argument on evidence, no fuffrage could perhaps be more decifive of its merits than that of one of the greateft lawyers, and indeed one of the ableft men that ever fat on the woolfack of England, the late Lord Chancellor Hardwicke, who declared Mr Tytler's Inquiry to be the beft concatenation of circumftantiate proofs brought to bear upon one point that he had ever perufed. What effect that body of evidence, or the arguments deduced from it, ought to have upon the minds of thofe to whom the fubject may become matter of inveftigation, we do not prefume to determine. The opinion of the late Dr Henry, author of the Hiftory of Great Britain on a New Plan, may perhaps be thought neither partial nor confident. He fays, in a letter to Mr Tytler, publifhed in the firft volume of Tranfactions of the Antiquarian Society of Scotland. That he would be a bold man who fhould now publifh an hiftory of Queen Mary in the fame ftrain with the two hiftorians (Mr Hume and Dr Robertfon), whofe opinions on the fubject the Inquiry had examined and controverted.

The moft exceptionable part of Mary's conduct, which, though it may admit of an apology, cannot be vindicated,

vindicated, is her marriage to Bothwell; and for that marriage Mr Tytler made an apology, founded on facts, which he would be a daring or very bigotted man who would attempt to controvert. See the article already referred to.

Besides the *Historical Inquiry*, and the *Dissertation on the Marriage of Queen Mary with the Earl of Bothwell*, our author published several other works on historical and literary subjects; of which the first was, the *Poetical remains of James I. King of Scotland*, consisting of *the King's Quhair*, in six cantos, and *Christ's Kirk on the Green*; to which is prefixed a dissertation on the Life and Writings of King James, in one volume 8vo, printed at Edinburgh in 1783. This dissertation forms a valuable morsel of the literary history of Europe; for James ranked still higher in the literary world as a *poet*, than in the political world as a *prince* (A). Great justice is done to his memory in both respects in this dissertation: and the two morsels of poetry here rescued from oblivion will be esteemed by men of taste as long as the language in which they are written can be understood.

2. "A Dissertation on Scottish Music," first subjoined to Arnot's history of Edinburgh. The simple melodies of Scotland have been long the delight of the natives, many of which, to them, convey an idea of pathos that can be equalled by none other; and are much admired by every stranger of musical talents who has visited this country. They have a powerful effect, indeed, when properly introduced, as a relief, into a musical composition of complicated harmony. These are of two kinds, pathetic and humorous. Those who wish to receive information concerning this curious subject, will derive much satisfaction from the perusal of this dissertation. There is yet another kind of music peculiar to the Highlands of Scotland, of a more wild, irregular, and animating strain, which is but slightly treated here, and requires to be still more fully elucidated.

3. "Observations on the Vision, a poem," first published in Ramsay's Evergreen, now also printed in the Transactions of the Society of Antiquaries of Scotland. This may be considered as a part of the literary history of Scotland.

4. "On the Fashionable Amusements in Edinburgh during the last century," *ibid*. It is unnecessary to dwell on the light that such dissertations as these, when judiciously executed, throw upon the history of civil society and the progress of manners. Mr Tytler was likewise the author of N° 16. of the Lounger, a weekly paper, published at Edinburgh in the year 1786. His subject is the Defects of Modern Female Education in teaching the Duties of a Wife; and he treats that subject like a master.

On all Mr Tytler's compositions the character of the *man* is strongly impressed, which never, as in some other instances, is in the smallest degree contradicted by, or at variance with, the character of the *author*. He wrote what he felt, on subjects which he felt, on subjects relating to his native country, to the arts which he loved, to the times which he revered. His heart, indeed, was in every thing which he wrote, or said, or did. He had, as his family and friends could warmly attest, all the kindness of benevolence: he had its anger too; for benevolence is often the parent of anger. There was nothing neutral or indifferent about Mr Tytler. In philosophy and in history, he could not bear the coldness, or what some might call the temperance of scepticism; and what he firmly believed, it was his disposition keenly to urge.

His mind was strongly impressed by sentiments of religion. His piety was fervent and habitual. He believed in the doctrine of a particular Providence, superintending all the actions of individuals as well as the great operations of Nature: he had a constant impression of the power, the wisdom, and the benevolence of the Supreme Being; and he embraced, with thorough conviction, the truths of Christianity.

His reading was various and extensive. There was scarcely a subject of literature or taste, and few even of science, that had not at times engaged his attention. In history he was deeply versed; and what he had read his strong retentive memory enabled him easily to recal. Ancient as well as modern story was familiar to him; and, in particular, the British history, which he had read with the most minute and critical attention. Of this, besides what he has given to the public, a great number of notes, which he left in MS. touching many controverted points in English and Scottish history, afford the most ample proof.

In music as a science he was uncommonly skilled. It was his favourite amusement; and with that natural partiality which all entertain for their favourite objects, he was apt to assign to it a degree of moral importance which some might deem a little whimsical. He has often been heard to say, that he never knew a good taste in music associated with a malevolent heart: And being asked, What prescription he would recommend for attaining an old age as healthful and happy as his own? "My prescription (said he) is simple—short but cheerful meals, music, and a good conscience."

In domestic life, Mr Tytler's character was particularly amiable and praise worthy. He was one of the kindest husbands and most affectionate fathers. At the beginning of this account, we mentioned his having lost, at an advanced period of life, an excellent wife, and a son and a daughter both grown to maturity, who merited and possessed his warmest affections. The temper of mind with which he bore these losses, he has himself expressed in a MS. note, written not long before his death; with which, as it conveys a sentiment equally important in the consideration of this life, and in the contemplation of that which is to come, we shall conclude the present memoir: "The lenient hand of time (says he, after mentioning the death of his wife and children), the lenient hand of time, the affectionate care of my remaining children, and the duty which calls on my exertions for them, have by degrees restored me to myself. The memory of those dear objects gone before me, and the soothing hope that we shall soon meet again, is now the source of extreme pleasure to me. In my retired walks in the country I am never alone; those dear shades are my constant companions! Thus what I looked upon as a bitter calamity, is now become to me the chief pleasure in life."

U, V.

(A) There is a beautiful historical picture of this prince playing on the harp, with his queen and a circle of his courtiers listening to the music, by Graham, in London; one of the most eminent artists of the age.

U, V.

Vacuum
||
Vanda.

VACUUM Boyleanum, is the approach to a real vacuum, to which we can arrive by means of the air pump.

Torricellian Vacuum, is the most complete vacuum which we can make by means of the torricellian tube. See Barometer, and Pneumatics, *Encycl.*

VADE-mecum, the title given to such books as men of particular professions, having frequent occasion to consult, may easily carry about with them. Thus a small volume, published in the beginning of the 18th century, giving an account of the ancient and present church of England, and of the duties, rights, privileges, and hardships of the clergy, is known by the title of *the Clergyman's Vade mecum.*

VAKEEL, a minister agent, or ambassador.

VALGUS, *Bow* or *Bandy Legged.* Some children are bow legged from their birth; others become so from setting them on their feet too early. The tibia of some is crooked; the knees of others are distorted; from a fault in the ankle, the feet of some are turned inwards, these are called *vari;* and in others they turn outwards, these are called *valgi.* The best method of preventing these disorders in weakly children, is to exercise them duly, but not violently; by dancing or tossing them about in one's arms, and not setting them much on their feet, at least not without properly supporting them: if the disorder attends at the birth, or increases after it is begun, apply emollients, then apply boots of strong leather, wood, &c. as required to dispose the crooked legs gradually to a proper form: or other instruments may be used instead of boots, which, when not too costly, are usually to be preferred. Slighter instances of these disorders yield to careful nursing without instruments.

VANDA, the Indian name of a plant of the genus Epidendrum: which see, *Encycl.* The *vandà* is thus described by Sir William Jones.

"Cal. *Spathes* minute, straggling. Cor. *Petals* five, diverging, oval oblong, obtuse, wavy; the two lowest larger; the three highest equal, bent towards the nectary. *Nectary* central, rigid: *Mouth* gaping, oblique: *upper lip* shorter, three parted, with a polished honey-cup; *under lip* concave in the middle, keeled above, with two smaller cavities below, two processes at the *base* incurved, hollow, oval pointed, converging, honey-bearing. Stam. *Filaments* very short. *Anthers* round, flattish, margined, covered with a lid, easily deciduous from the *upper lip* of the nectary. Pist. *Germ.* beneath long, ribbed, contorted with curves of opposite flexure. *Style* very short, adhering to the *upper lip. Stigma* simple. Per. *Capsule* oblong conic, wreathed, six keeled, each with two smaller keels, three-celled, crowned with the dry corol. Seeds innumerable, like fine dust affixed to the *receptacle* with extremely fine hairs, which become thick wool. *Scapes* incurved, solitary, from the cavity of the leaf, at most seven flowered; pedicles alternate. *Petals* milk white externally, transparent; brown within, yellow-spotted. *Upper lip* of the nectary snow white, *under lip* rich purple, or light crimson, striated at the base, with a bright yellow gland, as it seems, on each process. The flowers gratefully fragrant, and exquisitely beautiful, looking as if composed of shells, or made of enamel; crisp elastic, viscid internally. *Leaves* sheathing, opposite, equally curved, rather fleshy, sword-form, retuse in two ways at the summit, with one acute point. *Roots* fibrous, smooth, flexible; shooting even from the top of the leaves."

Vandalia,
Vandermonde.

This lovely plant attaches itself chiefly to the highest *Amras* and *Bilvas* (the *Mangifera* and *Cratæva* of Lin.); but it is an air-plant, and lives (says the President) in a pot *without earth or water*: its leaves are excavated upwards, to catch and retain dew.

VANDALIA, a duchy of Farther Pomerania, subject to the king of Prussia. Stolpen is the capital.

Vandalia, a country in Germany, in the circle of Lower Saxony and duchy of Mecklenburg. It lies between the bishopric and duchy of Schwerin, the lordships of Stocrock and Stargard, Pomerania, and the marquisate of Brandenburg; and is 75 miles in length and 7 in breadth. It contains several small lakes, and the principal town is Gustrow.

VANDERMONDE, member of the National Institute of Sciences and Arts, was born at Paris in the year 1735. He devoted his youth to self-instruction; and even at the age of thirty was far enough from suspecting that he was destined to instruct others in his turn. Chance brought him near to the celebrated Fontaine. That sexagenary geometrician easily divined the progress which Vandermonde would one day make in the mathematics; in him he anticipated, as it were, a successor to himself; he patronised and caressed him, let him into the secret of his researches, calculations, inventions, of that lively enjoyment which profound speculation gives to an elevated attentive mind; and which, blended with the sweets of tranquillity, the charms of retreat, and the consciousness of success, becomes often a sort of passion, as felicitous as durable. All that time Fontaine, whose attention was again directed to the researches which he had added to those of Jean Bernoulli, relative to the then famous question *of the tautocrones*, had the glory to be vanquished only by D'Alembert and La Grange. Vandermonde, a witness to this combat, necessarily illustrious, animated by the honour which he saw annexed to that glorious defeat, enchanted with the sight of Fontaine, as happy, in spite of his age, from his love of geometry, as a youth of twenty could be with a sentiment less tranquil, thought he should insure his happiness for ever, by yielding to a passion which the ice of age could not extinguish; in a word, he devoted himself to geometry.

His labours, however, were for some time secret; and perhaps the public would never have enjoyed the benefit of any of his works, if another geometrician (whose name, says Lacepede, cannot be pronounced, in this place, without a mixture of interest and regret) had not inspired him with a consciousness of his own strength, and courage to display it. Fontaine had already devoted him to geometry; Dulejour exhorted him to penetrate even into its sanctuary. In brief, he presented himself

himſelf to the Academy of Sciences, into which he was admitted in 177 ; and in that very year juſtified the ſuffrages of his aſſociates, by a paper which he publiſhed relative to the reſolution of equations.

From the 16th century the method of reſolving equations of the four firſt degrees has been known, and ſince that time the general theory of equations has received great improvements. In ſpite, however, of the recent labours of many great geometricians, the ſolutions of equations of the fifth degree had in vain been attempted. Vandermonde wiſhed to conſolidate his labours with thoſe of other illuſtrious analyſts; and he propoſed a new theory of equations, in which he ſeems to have made it particularly his buſineſs to ſimplify the methods of calculation, and to contract the length of the *formulæ*, which he conſidered as one of the greateſt difficulties of the ſubject.

This work was quickly followed by another on the problems called by geometricians *problems of ſituation*. It ſeems to have been the deſtiny of Vandermonde, as well as of Fontaine, who firſt initiated him into the myſteries of mathematical ſcience. to labour frequently upon ſubjects already handled by the greateſt maſter. In his firſt memoir he had ſtarted, ſo to ſpeak, in competition with La Grange and Euler; in his ſecond, with Euler and Leibnitz. This laſt was of opinion that the analyſis made uſe of in his time, by the geometricians, was not applicable to all queſtions in the phyſical ſciences; and that a new geometry ſhould be invented, to calculate the relations of poſitions of different bodies, in ſpace: this he called *geometry of ſituation* *. Excepting, however, one application, made by Leibnitz himſelf, to the game of *ſolitaire*, and which, under the appearance of an object of curioſity, ſcarcely worthy the ſublimity and uſefulneſs of geometry, is an example for ſolving the moſt elevated and important queſtions, Euler was almoſt the only one who had practiſed this geometry of ſituation. He had reſorted to it for the ſolution of a problem called the *cavalier*, which alſo appeared very familiar at firſt ſight, and was alſo pregnant with uſeful and important applications. This problem, with the vulgar, conſiſted merely in running through all the caſes of the cheſs board, with the *knight* of the game of cheſs; to the profound geometrician, however, it was a precedent for tracing the route which every body muſt follow, whoſe courſe is ſubmitted to a known law, by conforming to certain required conditions, through all the points diſpoſed over a ſpace in a preſcribed order. Vandermonde was chiefly anxious to find in this ſpecies of analyſis a ſimple notation, likely to facilitate the making of calculations; and he gave an example of this, in a ſhort and eaſy ſolution of the ſame problem of the cavalier, which Euler had rendered famous.

His taſte for the high conceptions of the ſpeculative ſciences, as blended with that which the *Amor patriæ* naturally inſpires for objects immediately uſeful to ſociety, had led him to turn his thoughts towards perfecting the arts converſant in weaving, by indicating a manner of noting the points through which are to paſs the threads intended to form the lines which terminate the ſurface of different regular bodies: accordingly a great part of the above memoir is taken up with this ſubject.

In the year following (1772) he printed a third memoir; in which he traced out a new path for geometers, diſcovering, by learned analytical reſearches, *irrational* quantities of a new ſpecies, ſhewing the ſquares of which theſe *irrationals* are the terms of the ſum, and pointing out a direct and general method of making in them all the poſſible reductions. Va der-

In the ſame year appeared his work on the Elimination of unknown Quantities in Algebra. This elimination is the art of bringing back thoſe equations which include many unknown quantities, to equations which only contain one. The perfection of reſearches in this art would conſiſt in obtaining a general and particular *formula* of elimination in a form the moſt conciſe and convenient, in which the number of equations and their degrees ſhould be deſigned by indeterminate letters. Vandermonde, while he conſidered the geometers as very diſtant from this point, had ſome glimpſe of a poſſibility of reaching it, and propoſed ſome new methods of approaching nearer it.

In 1778, he preſented, in one of the public ſittings of the Academy, a new ſyſtem of harmony, which he detailed more fully in another public ſitting of 1780. In this ſyſtem, Vandermonde reduces the [illegible] of proceeding adopted until his time, to two principal rules, which thus become eſtabliſhed [illegible] all muſicians. Theſe two general rules, one on the ſucceſſion of according ſounds, the other on the arrangement of the parts, depend themſelves on a law more elevated, which according to Vandermonde, ought to rule the whole ſcience of harmony.

By the publication of this work, he ſatisfactorily attained the end he had propoſed to himſelf, and obtained the ſuffrages of three great men, repreſentatives, ſo to ſpeak, of the three great ſchools of Germany, France, and Italy; Gluck, Philidor, and Piccini.

With theſe labours, intermingled with frequent reſearches on the mechanic arts, as well as on objects of political economy. the attention of Vandermonde was taken up; when, July 14. 1789, the voice of liberty reſounded over the whole ſurface of France, and ſuddenly all the thoughts, as well as all the affections, of Vandermonde, were engaged on the ſide of what he called liberty.

He became ſo furious a democrate, ſo outrageous an enemy to every thing eſtabliſhed, that he concurred in the abolition of the Royal Academy, of which he had been ſo ambitious of becoming a member, and aſſociated himſelf cloſely with Robeſpierre, Marat, and the reſt of that atrocious gang of villains, who covered France with ruins, with ſcaffolds, and with blood. This part of Vandermonde's hiſtory is ſuppreſſed by his eulogiſt Lacepede, becauſe, forſooth, diſcuſſions on *political opinions* ought not, in his opinion, to be admitted into the ſanctuary of the ſciences.

In that ſanctuary he did not long remain. Soon after his atrocities, he was attacked by a diſorder in his lungs, which almoſt taking away his breath, manifeſted itſelf by alarming ſymptoms, and conducted him by rapid ſteps to the tomb. He died in the end of the year 1795; a ſtriking inſtance of the wayward violence of the human mind, which even the love of ſcience could not keep at a diſtance from tumult and uproar.

VARENIUS (Bernard), a learned Dutch geographer and phyſician of the 17th century, who was author of the beſt mathematical treatiſe on geography, intitled, *Geographia Univerſalis, in qua affectiones generales Telluris*

ris explicantur. This excellent work has been translated into all languages, and was honoured by an edition, with improvements, by Sir Isaac Newton, for the use of his academical students at Cambridge.

VARIABLE, in geometry and analytics, is a term applied by mathematicians to such quantities as are considered in a variable or changeable state, either increasing or decreasing. Thus the abscisses and ordinates of an ellipsis, or other curve line, are variable quantities; because these vary or change their magnitude together, the one at the same time with the other. But some quantities may be variable by themselves alone, or while those connected with them are constant: as the abscisses of a parallelogram, whose ordinates may be considered as all equal, and therefore constant; also the diameter of a circle, and the parameter of a conic section, are *constant*, while their abscisses are *variable*. See FLUXIONS, *Encycl.*

VARIATION OF CURVATURE, in geometry, is used for that inequality or change which takes place in the curvature of all curves except the circle, by which their curvature is more or less in different parts of them; and this variation constitutes the quality of the curvature of any line.

1 Variolæ vaccinæ long known in Gloucestershire,

VARIOLÆ VACCINÆ, or *Cow-pox*, is the name commonly, though, as some people think, improperly, given to a very singular disease, which, for two or three years past, has occupied a great share of the attention of medical men. It has been many years prevalent in some of the great dairy counties in England, particularly Gloucestershire; and it has been long understood by the farmers and others in these counties, that it for ever exempts all persons who have been infected with it from the contagion of small pox.

It is very surprising that, though they knew this fact, and although no person had ever been known to die of the cow pox, they never thought of having recourse to a voluntary infection of this kind, in order to free themselves and their families from the possibility of being infected with the variolous poison, which so often proves mortal. In one case, indeed, communicated to Dr Pearson by Mr Downe of Bridport, the experiment was long ago tried by a farmer upon his own person, and with complete success: But this only makes it the more wonderful that his example should not have been followed.

2 And in the duchy of Holstein.

In the town of Kiel, however, in the duchy of Holstein, where the disease is said to be well known, as frequently affecting cows, we are told that children are sometimes inoculated with cow-pox (*Die Finnen*), with a view to preserve their beauty; but that the people in the country do not like this inoculation, because they pretend that it leaves behind it several disorders.

3 Vaccine inoculation introduced by Dr Jenner.

With these exceptions, Dr Jenner was the first person who introduced the vaccine inoculation; and to him the public are also indebted for the first careful and accurate investigation of this interesting subject. The following is his account of the origin and history of the disease, and of its characteristic symptoms.

4 Origin of the disease, according to him.

"There is a disease to which the horse, from his state of domestication, is frequently subject. The farriers have termed it *the grease*. It is an inflammation and swelling in the heel, from which issues matter possessing properties of a very peculiar kind, which seems capable of generating a disease in the human body (after it has undergone the modification which I shall presently speak of), which bears so strong a resemblance to the small pox, that I think it highly probable that it may be the source of that disease.

"In this dairy county (Gloucestershire), a great number of cows are kept, and the office of milking is performed indiscriminately by men and maid servants. One of the former having been appointed to apply dressings to the heels of a horse affected with *the grease*, and not paying due attention to cleanliness, incautiously bears his part in milking the cows with some particles of the infectious matter adhering to his fingers. When this is the case, it commonly happens that a disease is communicated to the cows, and from the cows to the dairy maids, which spreads through the farm until most of the cattle and domestics feel its unpleasant consequences. This disease has obtained the name of the cow pox. It appears on the nipples of the cows in the form of irregular pustules. At their first appearance they are commonly of a palish blue, or rather of a colour somewhat approaching to livid, and are surrounded by an erysipelatous inflammation. These pustules, unless a timely remedy be applied, frequently degenerate into phagedenic ulcers, which prove extremely troublesome. The animals become indisposed, and the secretion of milk is much lessened. Inflamed spots now begin to appear on different parts of the hands of the domestics employed in milking, and sometimes on the wrists, which quickly run on to suppuration, first assuming the appearance of the small vesications produced by a burn. Most commonly they appear about the joints of the fingers, and at their extremities; but whatever parts are affected, if the situation will admit, these superficial suppurations put on a circular form, with their edges more elevated than their centre, and of a colour distantly approaching to blue. Absorption takes place, and tumors appear in each axilla. The system becomes affected, the pulse is quickened, and shiverings, with general lassitude, and pains about the loins and limbs, with vomiting, come on. The head is painful, and the patient is now and then even affected with delirium. These symptoms, varying in their degrees of violence, generally continue from one day to three or four, leaving ulcerated sores about the hands, which, from the sensibility of the parts, are very troublesome, and commonly heal slowly, frequently becoming phagedenic, like those from whence they sprung. The lips, nostrils, eyelids, and other parts of the body, are sometimes affected with sores; but these evidently arise from their being needlessly rubbed or scratched with the patient's infected fingers. No eruptions of the skin have followed the decline of the feverish symptoms in any instance that has come under my inspection, one only excepted; and in this case a very few appeared on the arms: they were very minute, of a vivid red colour, and soon died away without advancing to maturation; so that I cannot determine whether they had any connection with the preceding symptoms.

5 Its appearance on the cow and the person who milks her.

"Thus the disease makes its progress from the horse to the nipple of the cow, and from the cow to the human subject.

"Morbid matter of various kinds, when absorbed into the system, may produce effects in some degree similar; but what renders the cow-pox virus so extremely singular is, that the person who has been thus affected 6 Its singularity,

Variola Vaccinæ.

is for ever after secure from the infection of the small-pox; neither exposure to the variolous effluvia, nor the insertion of the matter into the skin, producing this distemper.

17 Though it sometimes confounded with another dis

'It is necessary to observe, that pustulous sores frequently appear spontaneously on the nipples of cows; and instances have occurred, though very rarely, of the hands of the servants employed in milking being affected with sores in consequence, and even of their feeling an indisposition from absorption. These pustules are of a much milder nature than those which arise from that contagion which constitutes the true cow-pox. They are always free from the bluish or livid tint so conspicuous in that disease. No erysipelas attends them, nor do they shew any phagedenic disposition, as in the other case, but quickly terminate in a scab, without creating any apparent disorder in the cow. This complaint appears at various seasons in the year, but most commonly in the spring, when the cows are first taken from their winter food and fed with grass. It is very apt to appear also when they are suckling their young. But this disease is not to be considered as similar in any respect to that of which I am treating, as it is incapable of producing any specific effects on the human constitution. However, it is of the greatest consequence to point it out here, lest the want of discrimination should occasion an idea of security from the infection of the small-pox, which might prove delusive."

Dr Jenner adds, that the active quality of the virus from the horse's heels is greatly increased after it has acted on the nipples of the cow, as it rarely happens that the horse affects his dresser with sores, and as rarely that a milkmaid escapes the infection when she milks infected cows. It is most active at the commencement of the disease, even before it has acquired a pus-like appearance. Indeed the Doctor is rather induced to think that the matter loses this property entirely as soon as it is secreted in the form of pus, and that it is the thin darkish looking fluid only, oozing from the newly formed cracks in the heels, similar to what sometimes exudes from erysipelatous blisters, which gives the disease. He is led to this opinion, from having often inserted pus taken from old sores in the heels of horses, into scratches made with a lancet, on the sound nipples of cows, which has produced no other effect than simple inflammation.

He is uncertain if the nipples of the cow are at all times susceptible of being acted upon by the virus from the horse, but rather suspects that they must be in a state of predisposition, in order to ensure the effect. But he thinks it is clear that when the cow pox virus is once generated, the cows, when milked with a hand really infected, cannot resist the contagion, in whatever state their nipples may chance to be. He is also doubtful whether the matter, either from the cow or the horse, will affect the sound skin of the human body; but thinks it probable that it will not, except on those parts where the cuticle is very thin, as on the lips.

At what period the cow-pox was first noticed in Gloucestershire is not upon record. The oldest farmers were not unacquainted with it in their earliest days when it appeared upon their farms, without any deviation from the phenomena which it now exhibits. Its connection with the small pox seems to have been unknown to them. Probably the general introduction of inoculation first occasioned the discovery. Dr Jenner conjectures that its rise in that neighbourhood may not have been of very remote date, as the practice of milking cows might formerly have been in the hands of women only; and consequently the cows might not in former times have been exposed to the contagious matter brought by the men servants from the heels of horses. He adds, that a knowledge of the source of the infection is new in the minds of most of the farmers, but has at length produced good consequences; and that it seems probable, from the precautions they are now disposed to adopt, that the appearance of the cow-pox in that quarter may either be entirely extinguished or become extremely rare.

"With respect to the opinion adduced (Dr Jenner observes), that the source of the infection is a peculiar morbid matter arising in the horse; although I have not (says he) been able to prove it from actual experiments conducted immediately under my own eye, yet the evidence I have adduced appears to establish it.

"They who are not in the habit of conducting experiments, may not be aware of the coincidence of circumstances, necessary for their being managed so as to prove perfectly decisive; nor how often men engaged in professional pursuits are liable to interruptions, which disappoint them almost at the instant of their being accomplished; however, I feel no room for hesitation respecting the common origin of the disease, being well convinced that it never appears among the cows, except it can be traced to a cow introduced among the general herd which has been previously infected, or to an infected servant, unless they have been milked by some one who, at the same time, has the care of a horse affected with diseased heels."

The following case, which we also quote from Dr Jenner, would seem to shew that not only the heels of the horse, but other parts of the body of that animal, are capable of generating the virus which produces the cow-pox.

"An extensive inflammation of the erysipelatous kind appeared, without any apparent cause, upon the upper part of the thigh of a sucking colt, the property of Mr Millet, a farmer at Rockhampton, a village near Berkeley. The inflammation continued several weeks, and at length terminated in the formation of three or four small abscesses. The inflamed parts were fomented, and dressings were applied by some of the same persons who were employed in milking the cows. The number of cows milked was twenty four, and the whole of them had the cow-pox. The milkers, consisting of the farmer's wife, a man, and a maid servant, were infected by the cows. The man-servant had previously gone through the small-pox, and felt but little of the cow-pox. The servant maid had some years before been infected with the cow-pox, and she also felt it now in a slight degree: but the farmer's wife, who never had gone through either of these diseases, felt its effects very severely. That the disease produced upon the cows by the colt, and from them conveyed to those who milked them, was the *true* and not the *spurious* cow-pox, there can be scarcely any room for suspicion; yet it would have been more completely satisfactory had the effects of variolous matter been ascertained on the farmer's wife; but there was a peculiarity in her situation which prevented my making the experiment."

Subsequent

Variola Vaccinæ.

Dr Jenner's opinion of the origin of the disease controverted.

Subsequent authors have not been all disposed to adopt Dr Jenner's opinion that this disease derives its origin from the grease in horses. We have seen the Doctor himself allow that he has not been able to prove it decisively by actual experiments; and to establish a fact so contrary to all analogy, perhaps no weaker evidence ought to be admitted. The only other bestial disorder with which we are acquainted, which is capable of being communicated by contagion to the human species, is hydrophobia: but here the disorder is the same in man as in the animal from which he derives it; and the analogy holds good in the propagation of the vaccine disease from the cow to her milker. But that the discharge from a local disease in the heel of a horse should be capable of producing a general disorder in the constitution of a cow, with symptoms totally different, and that this new disease once produced should be capable of maintaining an uniform character in the cow and in man, seems a much greater departure from the ordinary proceedings of Nature. We are very far from saying that this is impossible; for little indeed do we know of what Nature can or cannot do. All we mean to say is, that a fact so very extraordinary ought not to be hastily admitted.

In Holstein, we are told that the farmers do not know of any relation existing between the grease and the cow pox, at least a person who resided three years in that country never heard of any. This, however, is certainly no proof. The same communication which contains this remark (a letter from Dr De Carro of Vienna to Dr G. Pearson) adds, "that in great farms men do not milk cows, but that in the smaller ones that happens very often; that a disease of horses, called *mauke* (true German name for *grease*), is known by all those who take care of them; that old horses particularly, attacked with the mauke, are always put in cow's stables, and there are attended by women; and that it is particularly in harvest that men in small farms milk cows." It must be allowed, then, that in this situation, supposing Doctor Jenner's opinion well founded, the cow-pox was naturally to be looked for, and here accordingly we find it. The question is certainly of no real utility, and therefore it has very properly been less attended to than other points respecting this disorder which lead to important practical conclusions.

Of all the questions which have arisen relative to the cow pox, there is none so interesting, and luckily there is none which has received so full a discussion, or so satisfactory an answer, as the one we are now about to consider. Are those persons who have once had the cow-pox effectually and for ever secured against the variolous contagion?

9
A previous attack of this disease renders the body unsusceptible of small-pox.

Dr Jenner, in his first publication, was decidedly of opinion that a previous attack of this disorder rendered the human body for ever unsusceptible of the variolous virus; and besides the universal popular belief in the countries where cow-pox is known, he brought forward a number of cases in support of his assertion. By some of these it appeared that persons who had been affected with the cow-pox above twenty or thirty years before, continued secure against infection, either by the effluvia from patients under small-pox, or by inoculation. But along with this opinion he entertained other two, which, to many people, appeared so surprising as to take away all credit from the former. The first was, that a previous attack of small-pox did not prevent a subsequent attack of cow pox; and the second was perhaps still more wonderful, that the cow pox virus, although it rendered the constitution unsusceptible of the small pox, should nevertheless leave it unchanged with respect to its own action, for that the same person is susceptible of repeated attacks of the cow-pox.

These opinions have been submitted to the test of very extensive experience by a variety of intelligent practitioners; and we think there can now be little doubt that the two last are erroneous, while the truth of the first has been established by an immense body of incontrovertible evidence.

The opinions that a person who has had the small-pox may afterwards have the cow pox, and that the same person may have the cow pox more than once, probably arose from the distinction between the local effects of the vaccine virus, and the general disorder of the constitution not having been sufficiently attended to. It is generally admitted, that in the inoculated small-pox the local affection may go so far as that a pustule shall arise on the part, containing matter capable of communicating the true small-pox to others, and yet, if no general affection of the constitution takes place, the patient is not secure from the disorder. In like manner, there are cases upon record which prove that a person may, after having had the small pox, have a local affection produced by inoculation, in which true variolous matter shall be formed capable of communicating both the local and constitutional symptoms of small-pox to others; and nurses, when much exposed to variolous contagion, often have an eruption resembling small-pox upon such parts of their skin as have been exposed to the action of the virus, though they have formerly undergone the disease. Yet there is probably no person at this day who will go so far as to assert that the same person can have the specific variolous fever more than once.

The case seems to be precisely the same with respect to cow-pox. Doctor Pearson and others have inoculated a number of persons after they have had the small-pox with the vaccine virus, and have produced only the local affection; and by the same test it is ascertained that the same person cannot more than once have the constitutional symptoms of the cow-pox. Dr Woodville indeed tells us that he has seen one case of genuine cow-pox pustule and specific fever in a constitution which had previously suffered the small-pox. There can be no higher authority on this subject than that of Dr Woodville; and if he had actually seen his patient in the small pox as well as the cow pox, we should have admitted this single case as completely decisive of the question. But the only evidence of this person having had the small-pox, is the assertion of the patient that he had it *when a child*. This we can by no means sustain as conclusive in opposition to the Doctor's own experience, as well as the experience of Dr Pearson.

That the milkers are subject to repeated attacks of, the local symptoms of cow pox, whether they have had the small-pox or not, is certain. In the case of the farmer's servants at Rockhampton, which we have quoted above from Dr Jenner, one of whom had previously undergone the small pox, and the other the cow-pox, and both of whom were afterwards infected by

Variolæ Vaccinæ. by the cow-pox *in a slight degree*, it seems reasonable to conclude that the local symptoms only were present in the last attack. We may at the same time observe, that in a case of this kind, where a very painful ulcer is produced in a very sensible part, this may probably be attended by an increased frequency of pulse; yet if this has not the specific marks of the cow pox fever, we should not say that such a person has the disorder constitutionally.

11 Success of vaccine inoculation. With respect to the principal proposition, that the specific fever of cow-pox renders the constitution unsusceptible of the variolous fever, we think no doubt now remains. Above 1000 persons who have undergone the vaccine inoculation have been afterwards inoculated with variolous matter, which has produced no other than local effects. Besides these, there have been a vast number inoculated by private practitioners in different parts of the kingdom, the result of which has not been reported. But we may safely suppose, that if any one of them had afforded a conclusion opposite to the one now generally admitted, it would have been communicated to the public.

We must not, however, conceal one seemingly well authenticated case which has lately occurred, and which, so far as it goes, certainly militates against this conclusion, and which, we doubt not, will be eagerly caught at by the opponents of the new practice. We quote it from the Medical and Chirurgical Review for September 1800.

12 A seemingly well authenticated exception. "Mr Malim, surgeon of Carey Street, London, inoculated a child, two years and an half old with vaccine matter procured from Dr Jenner. On the third day there were sufficient marks of the action of the virus, and from this time to the end of the disease the local affection proceeded regularly and without interruption. On the eighth day the child complained of headache and sickness; had a quick pulse, white tongue, and increased heat, with an enlargement and tenderness in the axilla. These symptoms subsided in the course of the next day, and the child remained well till the twelfth, when it had a very severe attack of fever, succeeded, the following day, by an irruption; the appearance, progress, and termination of which, left no doubt in the minds of several eminent practitioners of its being the small-pox. That it was really so, has been since clearly proved by inoculation. There was a child ill of small pox in the house at the time the above inoculation of cow-pox was performed."

The Reviewers justly remark, that the history is defective in not describing more minutely the appearances of the inoculated parts at the different stages, as well as in not mentioning the length of time that the matter had been taken previous to being used. Both these points are the more important, as a suspicion naturally arises, that the local affection which succeeded the vaccine inoculation was not the genuine cow-pox pustule, but one of the spurious kind, which had not the power of destroying variolous susceptibility. The matter having been furnished by Dr Jenner, no doubt, renders this supposition the less probable; but if it was either long or improperly kept after it came out of his hands, it may have undergone a material change, by putrefaction or otherwise. Dr Jenner mentions an instance of a practitioner, who had been accustomed to preserve variolous matter in a warm pocket; a situation favourable for producing putrefaction in it. This matter, when inserted, was found to produce inflammation, swellings of the axillary glands, fever, and sometimes eruptions; but not of the true variolous kind, as patients thus inoculated were found still susceptible of the small-pox contagion. It is surely a possible supposition, tho' merely a conjecture, that the vaccine matter in Mr Malim's case had undergone some such change.

The case however, is in several respects an interesting one. As it has been supposed that variolous contagion, communicated in the form of exhalation does not affect the constitution in less than fourteen or fifteen days, and as the vaccine matter, communicated by inoculation, produces its specific effects some days earlier, it has been suggested, that wherever a person has been accidentally exposed to variolous effluvia, we should endeavour to anticipate the small-pox by immediately inoculating with the vaccine virus. But if there be nothing falacious in the above case, it appears that this measure would not stop the progress of the small pox, but that our patient would incur the additional danger of having two diseases instead of one.

At all events, it must be allowed that this child had been infected by the small-pox before the vaccine matter had begun to produce its specific effects, and probably even before the inoculation. Thus the small-pox may be considered as having begun before the cow-pox; and though we should be forced to allow that, matters being thus situated, the latter disorder could not prevent the farther progress of the former, it by no means follows, that when the cow pox has fairly run its course, the constitution is still susceptible of small-pox. The two diseases must have existed in this patient at the same time, though the one was in a latent state during the active stage of the other. 13 Probably accounted for.

This solitary case, then, is by no means conclusive, and certainly is not sufficient to outweigh the immense mass of concurring evidence which is opposed to it.

We proceed now to another highly important branch of our subject—the comparison of the advantages and disadvantages of the two diseases, with a view to the practice of inoculation. 14 Advantages of the practice.

Notwithstanding the immense number of cases in which the inoculation of the cow-pox has been tried, we are not yet fully qualified to appreciate the value of the new practice; because the disease has varied very much in severity, and even in its most remarkable symptoms, and that without any cause which has yet been discovered.

Dr Jenner's account of the disease gave us reason to think that the local affection in cow-pox was more severe than in the inoculated small-pox: That the fever in this disease was never attended with dangerous symptoms: that those symptoms which affect the patient with severity are entirely secondary, excited by the irritating processes of inflammation and ulceration: that the disease was not attended with any eruption resembling small-pox: and that the sore produced by the inoculation was apt to degenerate into a very distressing phagedenic ulcer, which required to be treated with applications of a caustic nature, of which he found the unguentum hydrargyri nitrati the most useful.

Soon after Dr Jenner's publication, the attention of medical men was forcibly drawn to the subject; and several eminent practitioners in London, particularly Dr George

Variolæ Vaccinæ.

George Pearson, and Dr Woodville physician to the small-pox and inoculation hospitals, immediately began to practise the vaccine inoculation. The latter gentleman soon published an accurate and candid account of the effect of this virus upon 200 patients, with a table of the results of above 500 cases in which the inoculation was performed.

15
Anomalies in the progress of the disease.

It is very remarkable, that in none of these cases did the inoculated part ulcerate in the manner described by Dr Jenner, nor did the inflammation ever occasion any inconvenience, excepting in one instance, in which it was soon subdued by the aqua lythargyri acetati. The general affection of the constitution, on the other hand, though in a great majority of cases it was very slight, yet, in some instances, was severe. An eruption, exactly resembling small-pox, was, contrary to expectation, a very common occurrence, and in some the pustules were not fewer than 1000; and although in these cases the disease was still unattended with secondary fever, yet the febrile symptoms which took place from the commencement were considerable, and even alarming, as sometimes also happens with the inoculated small-pox.

Dr Woodville sometimes inoculated with matter from the primary sore in the arm, and sometimes with matter taken from the pustular eruption; and it appears from the table that a much larger proportion of those who were inoculated in the latter way had pustules, than of those who were inoculated either with matter immediately from the cow, or from the primary sore in the human body. There were 447 patients in all inoculated, either from the cow or from the primary sore; and of these 241 had pustules, and 206 had none. Sixty-two persons, on the other hand, were inoculated with matter from the pustules of ten different patients; and of these no fewer than 57 had pustules, and only 5 escaped without. Nor can it be said that this disproportion arose from these 10 patients having the disease in a more virulent form than ordinary, for matter was also taken from the primary sore in 4 of the 10, with which 48 were inoculated; of whom 27 had pustules, and 21 had none: whereas, of 9 persons who were inoculated with matter from the pustules of these same 4, only 2 escaped without pustules. This observation corresponds also with Dr Pearson's experience.

Although these eruptions have been met with by other practitioners, yet they certainly appear very rarely in private practice. Dr Woodville, for this reason, considers them, in a more recent publication, as the effect of some adventitious cause, independent of the cow-pox: And this he supposes to be the variolated atmosphere of the hospital, which those patients were necessarily obliged to inspire during the progress of the cow-pox infection. This opinion, however, does not seem to agree well with his former remark, which, as we have said, is confirmed by Dr Pearson, that eruptions rarely took place, if care was taken to avoid matter for inoculation from such as had pustules; a fact that cannot be explained on such a supposition. Neither is this idea reconcileable with what he also tells us, that the proportion of cases in the hospital attended with pustules has been of late only three or four in a hundred.

This change in the appearances of the disease in the hands of different practitioners, and even of the same practitioner at different times, is one of the most unaccountable circumstances respecting this singular disorder. There is some curious information on this subject, contained in a letter from Mr Stromeyer of Hanover to Mr Hannehmaun.

"This year (says he) we have inoculated 40 persons, as well with the vaccine matter received of Dr Pearson as with that from Dr Jenner; all of whom underwent the disease properly.

"Betwixt the London and Gloucester vaccine matter, it appears to me there subsists an essential difference. The London matter produces frequently an eruption of small pimples; but they disappear within a day or two at farthest. Dr Pearson calls these eruptions *pustules*.—The Gloucester matter has never produced this effect here; but *frequently occasioned ulcerations of the inoculated part, of a tedious and long duration; which the latter never did:* on account of which I now only make use of Dr Pearson's vaccine matter. The nettle-fever-like eruptions I have observed several times, but never that sort of eruption, repeatedly noticed in London, which so much resembles the small pox."

If these observations of Mr Stromeyer should be confirmed by the experience of others, they would go far to explain the difference which the London practitioners have found in this disease from the account given of it by Dr Jenner, notwithstanding the absence of the eruption resembling small-pox at Hanover. We believe an interchange of vaccine matter has once or twice taken place between London and Gloucestershire. Is it since that period that the eruption has been less frequent at London? Dr Pearson is inclined to suppose, that the comparative severity of the disease at London, during the first winter, arose rather from the difference in the human constitution at the different seasons of the year, than from any change in the state of the vaccine matter.

16
Mortality for the old practice over-rated by the advocates for the new.

In comparing the degree of danger from the inoculation of cow-pox with that arising from the inoculated small-pox, we are convinced that Dr Pearson greatly over-rates the mortality in the latter disorder. He supposes it to be no less than one in 200. Dr Moseley, on the other hand, who is a violent opponent of the vaccine inoculation, asserts, that he has inoculated several thousands with variolous matter, in Europe and the West Indies, without ever losing a patient, and that several other persons, whom he knows, have done the same, with the same success. We are afraid, however, that the experience of other inoculators does not afford so favourable a result. We believe that in this country the mortality is often occasioned by improper treatment; and from comparing the accounts which we have received from practitioners of extensive experience, and undoubted veracity, we believe that, where the treatment is proper from the beginning, the symptoms very rarely arise to an alarming height, and that the mortality is not so great as one in 600. And this estimate nearly corresponds with Dr Woodville's very great experience. It must be allowed, that patients in an hospital are subject to some disadvantages, which may be avoided in private practice; yet, out of the last 5000 cases of variolous inoculation at the inoculation hospital, prior to the publication of the Doctor's reports, the mortality did not exceed one in 600.

Notwithstanding this statement, however, we are happy

py to ſay, that the danger in the vaccine diſeaſe is ſtill much leſs. Dr Pearſon tells us, that in little more than ſix months after the new inoculation was introduced into London, which includes the period at which the cow-pox aſſumed the moſt unfavourable appearance, 2000 perſons at leaſt underwent the operation; of theſe, one only, an infant at the breaſt, under the care of Dr Woodville, died. In this ſolitary fatal caſe, the local tumor was but very inconſiderable; and the eruptive ſymptoms took place on the ſeventh day, when the child was attacked with fits of the ſpaſmodic kind, which recurred at ſhort intervals, with increaſed violence, and carried it off on the eleventh day after the cow-pox matter had been inſected into its arm, and after an eruption of about 80 puſtules had appeared.

17 Great ſucceſs of the new inoculation.

Since that time a much greater number, amounting certainly to ſeveral thouſands, have been inoculated with cow pox in different parts of Great Britain and on the continent. Among theſe, not one fatal inſtance, that we have heard of, has occurred.

But even if the danger to the individual from the ſmall-pox and from the cow-pox were equal, there is an important advantage to the public attending the latter, which we think would alone be ſufficient to intitle it to a preference—It is not capable of being propagated by the effluvia ariſing from the bodies of perſons infected with it. There are many ſituations in which a prudent ſurgeon will be reſtrained from inoculating with ſmall pox, leſt the contagion ſhould ſpread to other people, who may be either prevented by prejudice from ſubmitting to the operation, or in whom it would be obviouſly improper, from the circumſtances of age, teething, or the preſence of ſome other diſeaſe. Here the cow-pox virus may be ſubſtituted with great propriety. It is chiefly from this quality that the cow pox bids fair to extirpate the ſmall-pox entirely.

This valuable property of the vaccine diſorder is not, however, to be admitted without ſome limitation. When it produces numerous puſtules on the body, Dr Woodville tells us, that the exhalations they ſend forth are capable of affecting others, in the ſame manner as the ſmall-pox. Two inſtances of caſual infection in this way have fallen under his obſervation. In one, the diſeaſe was ſevere, and the eruption confluent; in the other, the diſeaſe was mild, and the puſtules few. It has been remarked, that the inoculated cow-pox is little, if at all, different from the diſeaſe when caſually caught. But, ſtrictly ſpeaking, the above are the only two caſes in which the diſeaſe has been communicated otherwiſe than by inoculation.

18 Whether the cow-pox and ſmall-pox ought to be conſidered as different diſeaſes.

The writers upon this ſubject are divided in opinion, whether the cow-pox and ſmall-pox ought to be conſidered as different diſeaſes, or whether they are merely varieties of the ſame diſeaſe.

They certainly, notwithſtanding the ſtrong analogy which ſubſiſts between them, differ from each other in ſeveral ſtriking particulars. The cow pox comes to man from the cow, and is capable of being carried back from him to that animal. Similar attempts with variolous matter have failed: in this reſpect, then, theſe two morbid poiſons are altogether different.

The local tumor produced by the inoculation of the cow-pox is commonly of a different appearance from that which is the conſequence of inoculation with variolous matter: for if the inoculation of the cow pox be performed by a ſimple puncture, the conſequent tumor, in the proportion of three times out of four, according to Dr Woodville, aſſumes a form completely circular, and it continues circumſcribed, with its edges elevated and well defined, and its ſurface flat, through every ſtage of the diſeaſe; while that which is produced from the variolous matter, either preſerves a peculiar form, or ſpreads along the ſkin, and becomes angulated, or irregular, or diſfigured by numerous veſiculæ. Another diſtinction ſtill more deciſive and general, is to be drawn from the contents of the cow pox tumor; for the fluid here formed very rarely becomes puriform; and the ſcab which ſucceeds is of a harder texture, exhibits a ſmoother ſurface, and differs in its colour from that which is formed by the concretion of pus. The appearances, however, are ſometimes ſo changed, that they can in no reſpect be diſtinguiſhed from thoſe which ariſe from the inoculation of ſmall-pox. We may alſo mention that the tendency of the ſore in the inoculated part to degenerate into a phagedenic ulcer does not occur in ſmall pox.

On the other hand, the points in which theſe two diſeaſes reſemble each other are very remarkable. When introduced into the body by inoculation, they affect the conſtitution in nearly the ſame length of time, and ſeem to be governed by nearly the ſame laws. They mutually deſtroy the ſuſceptibility of the body for the action of each other

Dr Pearſon, who thinks the diſeaſes ought to be conſidered as diſtinct ſpecies, nevertheleſs draws the following concluſions, as eſtabliſhed by experience.

"That in certain conſtitutions, or under the circumſtances of certain co operating agents, *the vaccine poiſon produces a diſeaſe reſembling the ſmall pox*; and of courſe the puſtule in the inoculated part is *very different from that of the vaccine pox ordinarily occurring*, and the eruptions *reſemble very much, if not exactly, ſome varieties of the ſmall-pox*: That in ſome inſtances theſe eruptions have occurred, although the inoculated part exhibited the genuine vaccine puſtule: That the matter of ſuch eruptive caſes, whether taken from the inoculated part, or from other parts, produces univerſally (A), or at leaſt generally, ſimilar eruptive caſes; and has not (he believes) been ſeen to go back, by paſſing through different conſtitutions, to the ſtate in which it produces what is called the *genuine vaccine diſeaſe*: That eruptions, of a different appearance from variolous ones, ſometimes occur in the true cow pox."

19 They are probably only varieties of the ſame diſeaſe.

From theſe facts we are ſtrongly inclined to think that the vaccine diſeaſe and the ſmall-pox ought merely to be conſidered as varieties of the ſame diſeaſe; and we have little doubt that they both derive their origin from the ſame ſource.

If Dr Jenner's opinion, that the vaccine diſeaſe is derived from *the greaſe*, were fully eſtabliſhed, we ſhould be diſpoſed to offer a conjecture, that the *ſmall-pox*, in coming from the horſe to man, may have paſſed thro' ſome

(A) We have ſeen that Dr Woodville's table contains a few exceptions to this rule, though it ſtrongly confirms the general truth of the propoſition.

some animal different from the cow, and may thus have undergone a modification similar to, but not exactly, the same with what takes place in the passage of the virus through the constitution of the cow.

But without having recourse to this conjecture, which is perfectly gratuitous, we are of opinion that the variations which have taken place in the cow pox within the last three years are sufficient to warrant a belief, that the small-pox may have originally been exactly the same disease, even in the human constitution, as the cow-pox is now; but that in a succession of ages, and from the operation of causes wholly unknown to us, it may have been changed to what we now see it.

We shall now conclude this article with a few practical remarks, which we hope may be of use to practitioners who mean to begin the vaccine inoculation.

20 Practical remarks.

It is of the utmost consequence that the matter employed should be the genuine vaccine virus. Dr Jenner points out the following particulars as sources of a spurious cow-pox: 1. That arising from pustules on the nipples or udder of the cow, which pustules contain no specific virus. 2. From matter, although originally possessing the specific virus, which has suffered a decomposition, either from putrefaction, or any other cause less obvious to the senses. 3. From matter taken from an ulcer in an advanced stage, though the ulcer arose from a true cow-pox. 4. From matter produced on the human skin from the contact of some peculiar morbid matter generated by a horse.

Many have remarked that inoculation with the vaccine matter is more apt to fail in communicating the infection than with variolous matter, especially if it be suffered to dry upon the lancet before it is used. This does not seem to depend upon the virus of the former being more volatile, but upon its becoming more hard and indissoluble upon exsiccation. Care should therefore be taken to moisten it a considerable time before it is used.

We have already noticed the danger that may arise from mistaking the local effects of the vaccine disease for its effects upon the constitution. To guard practitioners against this error, Dr Woodville makes the following remarks: " When a considerable tumor and an extensive redness take place at the inoculated part, within two or three days after the infectious matter has been applied, the failure of inoculation may be considered as certain as where neither redness nor tumor is the consequence. This rapid and premature advancement of the inflammation will always be sufficient to prevent the inoculator from mistaking such cases for those of efficient inoculation. But there are other circumstances under which I have found the inoculation to be equally ineffectual, and which, as being more likely to deceive the inoculator, require his utmost circumspection and discrimination. I here allude to cases in which it happens that though the local affection does not exhibit much more inflammation than is usual, yet neither vesicle nor pustule supervenes; and in which, about the sixth or seventh day, it rapidly advances into an irregular suppuration, producing a festering or crustaceous sore. Care, however, should be taken to distinguish this case from that in which the inoculated part assumes a pustular form, though it continues for one or two days only, when the same appearances follow as those above described; for I have experienced the latter inoculation to be as effectual as where the tumor has proceeded in the most regular manner."

" The efflorescence at the inoculated part, which seldom intervenes before the eighth, or later than the eleventh, day, is to be regarded as an indication that the whole system is affected; and if the patient has not felt any indisposition on or before its approach, he may be assured that there will not be any afterwards. When efflorescence does not commence till the eleventh day, it is almost always attended with more indisposition than when it occurs on the eighth or ninth day. The efflorescence is more frequent in young infants than in children advanced to three or four years of age; and the former have the efflorescence and the disease more favourably than the latter, insomuch that by far the greater part of them have no perceptible illness, and require no medicines. On the other hand, in adults, the cow-pox frequently produces headache, pain of the limbs, and other febrile symptoms, for two or three days, which are greatly relieved by a brisk purgative."

We would, upon the whole, recommend the vaccine inoculation to our medical readers as being an effectual preventative against the small-pox, and safer to the individual, while it is more advantageous to the public at large, in being less capable of propagation by contagion.

VECTOR, or RADIUS VECTOR, in astronomy, is a line supposed to be drawn from any planet, moving round a centre, or the focus of an ellipse, to that centre or focus. It is so called, because it is that line by which the planet seems to be carried round its centre; and with which it describes areas proportional to the times.

VEGETABLES. } See *Vegetable* SUBSTANCES in
VEGETATION. } this *Suppl.*

VENTILATION OF SHIPS is a matter of so great importance, that we would rather hazard the stating of an idle project for this purpose, than omit any thing which may be useful. We hazard nothing, however, in stating the following plan by Mr Abernethy, who candidly acknowledges that it is built upon the principles which we, together with the learned editor of Chambers's Cyclopædia, have borrowed from Dr Hailes. This plan consists merely in causing two tubes to descend from above the deck to the bottom of a vessel, or as low as ventilation is required; and which should communicate by smaller pipes (open at their extremities) with those places designed to be ventilated. There should be a contrivance for stopping these communicating pipes, so that ventilation may be occasionally prevented from taking place, or confined to any particular part of the vessel.

One of the principal air tubes should descend as near to the stern of the vessel as convenient, and the other as near to the stem.

Through that tube which is in the head, the foul air is to be extracted; and through that which is in the stern, the fresh air is to descend to the different decks and other apartments of the vessel.

The extraction of the air is easily effected in the following manner: Let a transverse tube be fitted to that which descends in the head of the vessel; it may be sunk within the level of the deck, so as to cause no inequality of surface. Let it be continued till it comes beneath

neath the fire-place, then ascend in a perpendicular direction through the fire, and open a little above it; or it may be made to communicate with the chimney. It would be more convenient if the fire was near the place where the tube rises through the deck; but the experiment must equally succeed, if the tube be made to descend again till it is beneath the common fire-place. The effect that will result from this contrivance is obvious; when the tube which passes through the fire is heated, the air will ascend with a force proportionable to its levity, and the ascending column can only be supplied from below, consequently it must come from all those parts of the ship with which the main tube communicates.

When the ports are open, the quantity of air thus exhausted from the ship will be supplied from all quarters; but if they were all shut, and the hatchways and other openings completely closed, the renewal of fresh air is made certain by means of the tube which descends in the stern. The main air tube, where it rises above the deck in the stern, should have an horizontal one fitted to it, which might be made to traverse, so that it could be turned to windward; it might also expand at its extremity like the mouth of a trumpet; and thus perfectly fresh air must enter, and the force of the gale would tend to impel it into the vessel.

When that part of the tube which passes through the fire is red hot, the draught which would be thus occasioned might perhaps be too great, and the open pipes which communicate with the decks might emit and imbibe the fresh air in so direct a stream, that it might be injurious to those persons within the current.

Mr Abernethy therefore thinks it would be better if those smaller pipes which lead from the main tubes were made to run along the decks, and communicate with them by numerous orifices. Two pipes opening into the main exhausting tube might be extended along the tops of the deck, in the angle formed between the sides and the cieling: and thus the air would be extracted equally from all parts, and in a manner not likely to occasion injurious currents. Some division of the stream of air which enters from the stern might also be made, if it were thought necessary.

Thus a very complete, and in no way injurious, ventilation may be obtained: the air in the vessel would be perfectly changed when the fire was strong, without expence or trouble; and a gradual and salubrious alteration of it might at all times be made, by a very little additional quantity of fuel. The air tubes should consist of separate joints, so that occasionally they might be taken to pieces; and to prevent their being injured or put out of order by rough usage, the copper pipes should be made of considerable strength, placed against the sides of the vessel, and even incased in wood.

In the Letters and Papers of the Bath Society, &c. we have the following description of a ventilator for preserving corn on ship board, by Thomas South, Esq;

Plate XLVII. Fig. 1. is a cylindrical air-vessel, or forcing pump, of lead, tin, or other cheap metal; its internal diameter being ten inches, and its length three feet; having a crutch-handled piston to work with, and an iron nosle, *viz.* a hollow inverted cone, two feet long, to condense the air, and increase its power in its passage downwards. This cylinder should be rivetted or screwed, by means of an iron collar or straps, to the deck it passes through, both above and below, as at *a a*; and should be farther secured by some holdfast near *b*, to keep it steady in working.

Fig. 2. is a bottom of wood, four inches and a half thick, with a projecting rim at its base, for the metal cylinder to rest on when cemented and screwed to the wood. The centre of this bottom is excavated, for the reception of the crown of the nosle. In the same figure the nosle is represented with its crown like a bowl dish, to condense the air gradually, without resistance, in its advance to the more contracted base of the inverted cone, *i. e.* the top or entrance of the nosle. About two-thirds down this nosle may be fixed a male screw, as *c c*, for the purpose hereafter mentioned.

N. B. The forcing-pump should be cased in wood, to protect it from outward bruises, which would prevent the working of the piston, and ruin its effects. The leather round the embolus should be greased when used.

Fig. 3. is a crutch-handle, fastened to the embolus A by its iron legs B, B. A is a cylinder of wood, cased with leather, so as to fit well, but glide smoothly, in the metal cylinder; having an opening as large as its strength will permit, for the free access of atmospheric air. C is a valve well leathered on its top, and yielding downwards to the pressure of the air when the piston is raised up. D is a cross bar of iron, to confine the valve, so that it may close instantly on the return of the piston downwards.

Fig. 4. is a tin pipe or tube, of less than four inches diameter, and of such length as, when fixed to the base of the cylinder, fig. 1. shall admit the nosle *d*, fig. 2. to within half an inch of the valve E, at the bottom of the wooden cylinder F, in fig. 4; which valve E will then yield to the pressure of air condensed in its passage through the nosle, and deliver it into the pipes below. This valve must be well leathered on its upper surface, and fastened with an hinge of leather to the cylinder it is meant to close: affixed to its bottom is the spindle G, passing through a spiral spring H, which, being compressed on the descent of the valve, will, by its elasticity, cause it to rise again, close the aperture above, and retain the air delivered beneath it. On connecting this cylinder with the upper end of the nosle, at *c c*, fig. 2. we must carefully prevent any lapse of air that way, by a bandage of oakum smeared with wax, on which to screw the cylinder, like the joints of a flute, air-tight. I is a bar of iron, having a rising in its centre, wide enough for the spindle to play through, but at the same time sufficiently contracted to prevent the passage of the spiral spring.

Fig. 5. is an assemblage of tin pipes, of any lengths, shaped suitably and conveniently to their situation in the ship, to the form of which, when shut into one another, they must be adapted; observing only, that the neck be straight for a length sufficient to admit the lower end of the cylinder, fig. 4. as high as the letter F, or higher.

Fig. 6. To the middle pipe, which runs along the bottom, should be fixed a perpendicular one, fully perforated, to convey the air more readily into the centre of the heap; and this may have a conical top, as represented in the Plate, perforated with a smaller punch to prevent the air from escaping too hastily. In large cargoes, two or three of these perpendiculars may be necessary;

Ventilation, Verden.

necessary; and each should be well secured by an iron bar *g*, screwed down to prevent their being injured by the shifting of the cargo in stormy weather or a rolling sea. The top of the conical cap of these pipes may reach two-thirds up the cargo.

Fig 7. is a valve of the same construction as that represented in fig. 4. but inclosed in a tube of brass, having a female screw at *ff*, adapted to the male screw *ee*, on the nosle fig 2. and may then be inserted into the head of the pipe fig. 5 This will add to the expence; but in a large apparatus is to be preferred, as a more certain security from lapse of air, than the junction of the tube fig. 4. to the neck *ee* in fig. 2.

N. B. *ee* is a neck of wood, making a part of the bottom fig. 2. whereon to secure the tube fig. 4. when applied to the nosle. The joints of the pipes, when put together for use, should be made air tight, by means of bees wax or some stronger cement, till they reach the bottom of the vessel, when there is no farther need of this precaution. The horizontal pipes should run by the side of the kelson the whole length of the hold. The tin plates of which K is made, should be punched in holes, like the rose of a watering pot, in two or three lines only at most, and then formed into a tube, with the rough side outwards L may have four or five lines of the like perforations. M, and the rest, should gradually increase in their number as they advance towards the middle of the hold, and continue fully perforated to the last pipe which should be closed at its end to prevent the ingress of the corn It is the centre of the cargo which most requires ventilating, yet air should pervade the whole. Like the trade-winds, it will direct its course to the part most heated, and, having effected its salutary purpose there, will disperse itself to refresh the mass.

Where the hatches are close-caulked, to prevent the influx of water, vent-holes may be bored in convenient parts of the deck, to be bunged up, and opened occasionally, from whence the state of the corn may be known by the effluvia which ascend when the ventilator is working.

The power of the ventilator is determined by the square of its diameter multiplied into the length of the stroke, and that again by the number of strokes in any given time.

The air-vessel or forcing pump, with the rest of the apparatus here described, is adapted to a vessel of 120 tons burden; but by lengthening the air vessel, extending its diameter to 14 inches, and adding 10 inches more to the length of the stroke, a power may be obtained of ventilating a cargo of 400 tons within the hour. If this machine be properly wrought for one hour every day, or even every two days, beginning the operations immediately when the corn is put on board, the cargo may be preserved from taint or injury of every kind during the longest voyage.

VERDEN, a duchy of Germany, in the circle of Lower Saxony. It is bounded on the east and south by that of Lunenburg; on the west, by the Weser and the duchy of Bremen; and on the north, by the duchies of Bremen and Lunenburg; extending both in length and breadth about 2[illegible] miles. It consists chiefly of heaths and high dry lands; but there are good marshes on the rivers Weser and Aller. In 1712, the Danes wrested this duchy from Sweden, and, in 1715, ceded it to the king of Great Britain, as elector of Hanover; which cession, in 1718, was confirmed by the Swedes. The inhabitants are Lutherans.

VERDIGRIS, or Acetite of Copper. See that article, *Encycl.* where an account is given of the process by which verdigris was long manufactured. A different, and more economical process, however, has for some years been practised in Montpellier, which is worthy of notice, because it may be adopted in this country by substituting the husks of gooseberries or currants for those of grapes.

In the manufacture of verdigris, the materials are copper and the husks of grapes after the last pressing. The copper is formed into round plates, half a line in thickness, and from twenty to twenty five inches in diameter. Each plate, at Montpellier, is divided into twenty-five laminæ, forming almost all oblong squares of from four to six inches in length, three in breadth, and weighing about four ounces. They are beat separately with the hammer on an anvil to smooth their surfaces, and to give the copper the necessary consistence. Without this precaution it would exfoliate, and it would be more difficult to scrape the surface in order to detach the oxydated crust. Besides this, scales of pure metal would be taken off, which would hasten the consumption of the copper.

The husks, which should not be too much pressed, are first made to ferment by being put into close vats, and the fermentation is generally completed in three or four days The time, however, must vary according to the temperature in which they are kept, and other circumstances. Whilst the husks are fermenting, a preliminary preparation is given to the copper plates. This consists in dissolving verdigris in water in an earthen vessel, and rubbing over each plate with a piece of coarse linen dipped in this solution. The plates are then immediately placed close to each other, and left in that manner to dry. Sometimes the plates are only laid on the top of the fermented husks, or placed under those which have been already used for causing the copper to oxydate It has been observed, that when this operation has not been employed, the plates grow black at the first operation, instead of becoming green. It is not, however, necessary to those which have been once used, and are to be used again.

When the plates are thus prepared, and the husks have been brought to ferment, the workmen try whether the latter are proper for the process, by placing under them a plate of copper, and leaving it buried there for twenty-four hours. If the plate, after this period, is found covered with a smooth green crust, in such a manner that none of the metal appears, they are then thought fit for being disposed in layers with the copper. On the other hand, if drops of water are observed on the surface of the plates, the plates are said to *sweat*, and it is concluded that the heat of the husks has not sufficiently subsided. They consequently defer making another trial till the next day. When they are assured that the husks are in a proper state, they form them into layers in the following manner:

The plates are all put into a box, which, instead of having a bottom, is divided in the middle by a wooden grate. The plates disposed on this grate are so strongly heated by a chaffing dish placed under them, that the woman employed in this labour is sometimes obliged to

Verdigris, Verdun

to take them up with a cloth, in order that she may not burn her hands. As soon as they have acquired that heat, they are put into jars in layers with the husks. Each jar is then closed with a covering of straw, and left to oxydate. Thirty or forty pounds of copper, more or less according to the thickness of the plates, are put into each jar. At the end of ten, twelve, fifteen, or twenty days, the jar is opened; and if the husks are white, it is time to take out the plates. The crystals are then seen detached, and of a silky appearance on their surface. The husks are thrown back, and the plates are put in what is called *relai*. For that purpose they are immediately deposited in a corner of the cellar on sticks ranged on the floor. They are placed in an upright position, one leaning against the other; and at the end of two or three days they are moistened, by taking them up in handfuls and immersing them in water in earthen pans. They are deposited quite wet in their former position, and left there for seven or eight days; after which they are once or twice immersed again. This immersion and drying are renewed six or eight times every seven or eight days. As the plates were formerly put into wine, these immersions were called *one wine*, *two wines*, *three wines*, according to the number of times. By this process the plates swell up, the green is nourished, and a coat of verdigris is formed on all their surfaces, which may be easily detached by scraping them with a knife.

This verdigris, which is called *fresh* verdigris, *moist* verdigris, is sold by the manufacturers to people who dry it for foreign exportation. In this first state it is only a paste, which is carefully pounded in large wooden troughs, and then put into bags of white leather, a foot in height and ten inches in diameter. These bags are exposed to the air or the sun, and are left in that state till the verdigris has acquired the proper degree of dryness. By this operation it decreases about 50 *per cent.* more or less according to its primitive state. It is said to stand proof by the knife, when the point of that instrument pushed against a cake of verdigris through the skin cannot penetrate it. White lead may be made by a similar process.

Crystallized VERDIGRIS is manufactured at Montpellier in the following manner: A vinegar, prepared by the distillation of sour wine, is put into a kettle, and boiled on the common verdigris. After saturation the solution is left to clarify, and then poured into another kettle of copper, where it is evaporated till a pellicle forms on the surface. Sticks are then immersed into it, and by means of some packthread are tied to some wooden bars that rest on the edge of the kettle. These sticks are about a foot long, and are split cross-wise nearly two inches at the end, so that they open into four branches, kept at about the distance of an inch from each other by small bags. The crystals adhere to these sticks and cover them entirely, forming themselves into groups or clusters, of a dark blue colour, and a rhomboidal shape. Each cluster weighs from five to six pounds. Three pounds of moist verdigris are required for one pound of the crystals; the undissolved residuum is thrown away.

VERDUN, an ancient, strong, and considerable town of France, in the department of Meuse, and late province of Lorrain, with a bishop's see, and a strong citadel. Its fortifications were constructed by the Chevalier de Ville and Marshal de Vauban. The latter was a native of this place. In 1755, great part of the cathedral was destroyed by lightning. Verdun was taken by the Prussians in 1792, but retaken by the French soon after. The inhabitants are noted for the fine sweetmeats they make. It is seated on the river Maese, which runs through the middle, 42 miles south-west of Luxemburg, and 150 east of Paris E. Lon. 5° 28' N. lat. 43° 9.

Vermifuge.

VERMIFUGE, a medicine which expels worms from the intestines. Of these medicines numbers are daily advertised in the newspapers as infallible, though the ingredients of which they are composed are carefully kept secret. We think it our duty therefore to assure our readers, that the medicines vended by quacks are generally the very same that would be prescribed by a regular physician for the disease in which they are pretended to be specifics, with this only difference, that the unseen and unprincipled quack generally prescribes them in more powerful doses than the regular physician deems safe for his patient. Thus Ching's famous worm medicine, which has been so strenuously recommended, is nothing more than mercury given in the very same form in which it is given by every physician; but Ching gives it in doses, which, though they have not injured the children of a bishop and a judge, we have *known* to *salivate* other children to the great hazard of their lives. It is indeed wonderful that parents should trust the health and the lives of their children to men whom they never saw, and whom they know to be not oppressed with an over delicate sense of honour, in preference to a man of science who has a character to support, and who is probably their friend, and almost always their acquaintance.

Of the different vermifuges, however, it must be confessed that the greater number are liable occasionally to fail. One of the most powerful which we have mentioned in the article MEDICINE, *Encycl.* is composed of the spiculæ of the *cowhage* or *cow-itch*; and since that article was published, it has come more into use, chiefly through the recommendation of Mr Chamberlaine surgeon. He says that a tea spoonful of the electuary (See MEDICINE, *Encycl.* p. 342.) may be safely given to a young child, and one or even two table spoonfuls to adults. The medicine is to be taken in the morning fasting; and the dose to be repeated for two or three mornings, after which a gentle purge completes the cure. This medicine, however, Mr Chamberlaine prohibits in every case where there is a tendency to inflammation in any part of the intestinal canal, or where the mucus has been carried off or greatly diminished by dysentery or any other cause.

Dr Haemmerlin of Ulm has lately recommended as a very powerful and safe vermifuge the coraline of Corsica, and says that it has been so used in that island with complete success from time immemorial. It is a fucus adhering to the rocks washed by the sea, and sometimes to the stones and shells thrown upon the shore. It is found in little tufts. It is generally of a yellow colour, with a reddish tincture. When dried, as it appears when offered for sale, it contains a strong smell of the sea. It consists of little cartilaginous stalks, with full threads, gradually cylindrical and tubulated. Its taste is salt and unpleasant. In the system of plants of Linnæus, it belongs to the class *cryptogamia*. Its most com-

mon

nish names are, sea rock moss; the Grecian herb; lemithochorton; and the coraline of Corsica. It is the *conferva helminthortos* of Schwendimann, and the *fucus helminthochorton* of Latourette. There is reason to think that all those species of fucus whose texture is soft and spungy, might be applied to the same medicinal uses. There is a sort of red coraline found in Sweden which, according to some writers, is a greater destroyer of worms than any other known substance; being not too strong for the stomach either of infants or of adults. Schwendimann asserts that the *conferva dichotoma* of Linnæus, which is found in the ditches in England, bears a strong analogy to the coraline of Corsica. Might not this conferva be tried as a vermifuge? The Corsican coraline is in great estimation in the pharmacopœias of the Continent, especially in that of Geneva, in which is given a recipe for preparing a syrup of it.

VERMONT, one of the United States of North America, bounded on the north by Canada; on the east, by the river Connecticut, which divides it from New Hampshire; on the south, by Massachussets; and on the west, by New York. It is about 155 miles long, and 60 broad, and is divided into 7 counties. A chain of high mountains, running north and south, divides this state nearly in the centre, between the river Connecticut and lake Champlain. The height of land is generally from 20 to 30 miles from the river, and about the same distance from the New York line. The natural growth upon this mountain is hemlock, pine, spruce, and other evergreens: hence it has always a green appearance, and, on this account, has obtained the descriptive name of Vermont, from the French *Verd Mont*, Green Mountain. On some high parts of this mountain, snow lies till May, and sometimes till July. The country is generally hilly, but not rocky. It is finely watered, the soil is very fertile, and there is not a better climate in the world. The inhabitants have very lately been estimated at 100,000. The bulk of them are emigrants from Connecticut and Massachusets. The principal town is Bennington, but the assembly generally hold their sessions at Windsor.

VESPA (See *Encycl.*). A new species of this genus of insects has been lately described by *Cuvier*, in a note read before the Philomathic Society of Paris. It has some resemblance to the *vespa nidulans* of Fabricius, which, as is generally known, is a native of certain parts of America. The nests of the vespa nidulans are constructed of a very fine web, of a very solid and pretty white paste. Their form is that of a bell closed upon all sides, excepting a narrow hole at the bottom; and they are suspended from the branches of trees.

The *vespa* described by Cuvier, which is a native of Cayenne in America, has in general more volume than the preceding species, and its paste is grey, coarser, less homogeneous, and less solid. The bottom of its nest also, in lieu of being shaped funnel like, is flat, and the orifice appears at one of the sides of the bottom part, and not in the middle. In the country where it is found, this species of wasp is called the *tatou fly* (*mouche tatou*). It differs greatly in form from that which Fabricius has described; it is all entirely of a shining black; the first articulation, or joint of its abdomen, is narrow, and in form of a pear; the second, larger than the others, is in form of a bell: the wings are brown. The following is the character assigned to it by Cuvier:

Vespatatua, Nigra, Nitida, Alis fuscis, abdomine pedicellato.

VESPERTILIO (see *Encyc.*) has been subjected to some cruel, but curious experiments, by the Abbé Spallanzani and M. de Jurine. The former of these philosophers having let loose several bats in a chamber perfectly dark, found that they flew about in it without any impediment, neither rushing against any thing in the apartment, nor touching the walls with their wings. This surprised him; but imagining that they were conducted by some glimpse of light which he did not perceive, he blindfolded them with a small and very close hood. They then ceased to fly; but he observed, at the same time, that this did not proceed from any deprivation of light, but rather from the constraint thence occasioned, especially when a hood of a very light texture was attended with the same effect.

He then conceived the idea of pasting up the eyes of the bats with a few drops of size or gum; but they still flew about in the same manner as if their eyes had been open. As this, however, was not sufficient, he pasted up the eyes of these animals with round bits of leather; and this even did not impede them in their flight.

That he might at length be certain of his object, he blinded them entirely, either by burning the cornea with a red hot wire, or by pulling out the pupil with a pair of small pincers, and scooping out the eye entirely. Not contented even with this precaution, he covered the wounds with pieces of leather, that the light might have no influence whatever on the remains of the organs which had been destroyed. The animals seemed to suffer very much by this cruel operation; but when they were compelled to use their wings, either by day or by night, and even in an apartment totally dark, they flew perfectly well, and with great caution, towards the walls, in order to suspend themselves when they wished to rest. They avoided every impediment, great or small, and flew from one apartment to another, backwards and forwards, through the door by which they were connected, without touching the frame with their wings. In a word, they shewed themselves as bold and lively in their flight as any other animals of the same species which enjoy the use of their eye-sight.

These experiments were repeated by M. Jurine, and with the same results. Spallanzani had supposed that the bat possessed some organ or sense which is wanting in the human species, and which supplies to these animals the place of vision; and Jurine determined to ascertain the truth or falsehood of this hypothesis by anatomical researches. During the course of these, he found the organ of hearing very great in proportion to that of other animals, and a considerable nervous apparatus assigned to that part. The upper jaw also is furnished with very large nerves, which are expanded in a tissue on the muzzle.

M Jurine then extended his experiments to the organ of hearing and that of smell. Having put a small hood on a long-eared bat, it immediately pulled it off, and flew. He stopped up its ears with cotton; but it freed itself in the like manner from that inconvenience. He then put into its ears a mastic of turpentine and wax. During the operation the animal shewed a great deal of impatience, and flew afterwards very imperfectly.

A long-eared bat, the ears of which had been bound up, flew very badly: but this did not arise from any pain

pain occasioned by the ligature; for when its ears were sewed up, it flew exceedingly well. In all probability the animal would have preferred having its ears bound up to having them sewed. Sometimes it flew towards the cieling, extending its muzzle before it settled.

M. Jurine poured liquid pomatum into the ears of a bat which enjoyed the use of its sight. It appeared to be much affected by this operation; but when the substance was removed it took flight. Its ears were again filled, and its eyes were taken out; but it flew then only in an irregular manner, without any certain or fixed direction.

The ears of a horse shoe bat, which had the use of its sight, were filled with tinder mixed with water. It was uneasy under the operation, and appeared afterwards restless and stunned; but it conducted itself tolerably well. On being blinded, it rushed with its head against the cieling, and made the air resound with strokes which it gave itself on the muzzle. This experiment was repeated on other bats with the like effects.

The tympanum of a large horse-shoe bat was pierced with a pin (*trois quart*). The animal appeared to suffer much from the operation, and fell down in a perpendicular direction when thrown into the air. It died next morning. The same effect was produced on piercing the tympanum of a long-eared bat with a needle.

The author then made very accurate researches on the difference between the organisation of the brain of these two kinds of bats; and, after a careful dissection, found that the eye of the long eared bat is much larger than that of the horse shoe bat, but that the optic nerve is proportioned to it. The outer part of the ear of the former is much larger than that of the latter, but the interior part is smaller.

The horse shoe bat is indemnified for this difference by a greater extension of the organ of smell, as evidently appears when the external elevations and irregularities of its muzzle are examined. When it is about to take flight, it agitates its nose much more than the long-eared bat.

From these experiments, the author concludes: *First*, That the eyes of the bat are not indispensably necessary to it for finding its way; *secondly*, That the organ of hearing appears to supply that of sight in the discovery of bodies, and to furnish these animals with different sensations to direct their flight, and enable them to avoid those obstacles which may present themselves.

VIBRATION FIGURES, are certain figures, formed by sand or very dry saw-dust, on a vibrating surface, which is connected with the sensation of sound in our organs of hearing. If the surface, on which the figures are to be formed, be strewed over with bodies easily put in motion, these, during the vibration, remain on the parts at rest, and are thrown from the parts in motion. The form of the parts at rest, which will be shewn by the sand that remains unmoved, and which, in general, is symmetric, is called a *vibration figure*. To produce such a figure, nothing is necessary but to know the method of bringing that part of the surface which you wish not to vibrate into a state of rest, and of putting in motion that which you wish to vibrate. On this depends the whole expertness of producing vibration figures.

Thus take a square piece of glass, pretty thin, and very smooth, such as that used for windows, about four or five inches over, or even more. Smooth it at the edges on a grinding-stone; strew a little saw-dust over its surface, and lay hold of it gently with the thumb and fore-finger of the left hand. Holding it thus by the middle, with the right hand rub a violin bow softly against one of its edges, drawing the bow either up or down in a direction almost perpendicular to the surface of the glass, and you will see a tremulous movement, and the whole dust leap about. If the bow be exactly in the middle of one of the sides, the dust will arrange itself almost in the direction of the two diagonals, dividing the square into four isosceles triangles. If the bow be applied at a quarter only of the distance of the one corner from the other, the dust will arrange itself in such a manner as to be found in the two diameters of the square, dividing it into four equal squares. At other times, when the bow deviates a little, the dust forms a figure like a double C, when the two letters are joined back to back. If the square be held by the two extremities of the diameter, opposite to that against which the bow is applied, the dust will form a kind of oval, one of the axes of which will be the [illegible] diameter. If the glass be of a circular figure, and be held by the middle, the dust will arrange itself in such a manner as to form the six radii of a regular hexagon. These discoveries were made by Dr Chladni, about the time that he invented the musical instrument, to which he gave the name of EUPHON (see that article, *Suppl.*); and as he found the vibration figures to vary in form with the various tones produced by the vibrating substances, a prosecution of his experiments may probably contribute to throw new light on the philosophy of musical sounds. We shall therefore give, from the 3d volume of *Neues Journal der Physik*, by Professor Gren, a few directions for making such experiments.

Vibration Figures, Vieta.

Any sort of glass may be employed, provided its surface be smooth; and when the plate has acquired the proper vibration, it should be kept in that state for some seconds, by continuing to rub it with the bow. The figures will thus be accurately formed.

Such plates should be procured as are pretty equal in thickness. It may be said, in general, that a plate the thinner it is will be so much the fitter for these experiments, though in this respect there is a certain minimum. In small plates, such as those that are circular, and not above six inches in diameter, the observation is general; but in larger plates too great thinness is prejudicial. Besides, it will be found that very thin glass is commonly very uneven, and must therefore be unfit for the experiments.

In practising the experiments, it will be proper to have plates of different sizes; and the sand employed should not be too fine. In other words, it must be of such a nature that when you incline the glass-plate it may readily roll off; because, in that case, it will be easily thrown from the vibrating parts. It will be of advantage that it be mixed with fine dust, which shews peculiar phenomena during the experiments, as it collects itself at one place of the vibrating part.

The plate must be equally bestrewed with sand, and not too thick, as the lines will then be exceedingly fine, and the figures will acquire a better defined appearance.

VIETA (Francis), a very celebrated French mathematician, was born in 1540 at Fontenai, or Fontenai-le-Comté, in Lower Poitou, a province of France. *Hutton's Mathematical Dictionary.*

He

Vieta. He was Master of requests at Paris, where he died in 1603, being the 63d year of his age. Among other branches of learning in which he excelled, he was one of the most respectable mathematicians of the 16th century, or indeed of any age. His writings abound with marks of great originality, and the finest genius, as well as intense application. His application was such, that he has sometimes remained in his study for three days together without eating or sleeping. His inventions and improvements in all parts of the mathematics were very considerable. He was in a manner the inventor and introducer of Specious Algebra, in which letters are used instead of numbers, as well as of many beautiful theorems in that science. He made also considerable improvements in geometry and trigonometry. His angular sections are a very ingenious and masterly performance: by these he was enabled to resolve the probem of Adrian Romanus, proposed to all mathematicians, amounting to an equation of the 45th degree. Romanus was so struck with his sagacity, that he immediately quitted his residence of Wirtzbourg in Franconia, and came to France to visit him, and solicit his friendship. His Apollonius Gallus, being a restoration of Apollonius's tract on Tangencies, and many other geometrical pieces to be found in his works, shew the finest taste and genius for true geometrical speculations.—He gave some masterly tracts on Trigonometry, both plane and spherical, which may be found in the collection of his works, published at Leyden in 1646, by Schooten, besides another large and separate volume in folio, published in the author's life-time, at Paris, in 1579, containing extensive trigonometrical tables, with the construction and use of the same, which are particularly described in the introduction to Dr Hutton's Logarithms, p. 4. &c. To this complete treatise on trigonometry, plane and spherical, are subjoined several miscellaneous problems and observations; such as, the quadrature of the circle, the duplication of the cube, &c. Computations are here given of the ratio of the diameter of a circle to the circumference, and of the length of the sine of 1 minute, both to a great many places of figures; by which he found that the sine of 1 minute is

between 2908881959
and 2908882056;

also the diameter of a circle being 1000, &c. that the perimeter of the inscribed and circumscribed polygon of 393216 sides will be as follows, viz. the

perim. of the inscribed polygon - 31415926535
perim. of the circumscribed polygon 31415926537

and that therefore the circumference of the circle lies between those two numbers.

Vieta having observed that there were many faults in the Gregorian Kalendar, as it then existed, composed a new form of it, to which he added perpetual canons, and an explication of it, with remarks and objections against Clavius, whom he accused of having deformed the true Lelian reformation, by not rightly understanding it.

Besides these, it seems a work, greatly esteemed, and the loss of which cannot be sufficiently deplored, was his *Harmonicon Cœleste*, which, being communicated to father Mersenne, was, by some perfidious acquaintance of that honest-minded person, surreptitiously taken from him and irrecoverably lost, or suppressed, to the great detriment of the learned world. There were also, it is said, other works of an astronomical kind, that have been buried in the ruins of time.

Vieta was also a profound decipherer, an accomplishment that proved very useful to his country. As the different parts of the Spanish monarchy lay very distant from one another, when they had occasion to communicate any secret designs, they wrote them in ciphers and unknown characters during the disorders of the league. The cipher was composed of more than 500 different characters, which yielded their hidden contents to the penetrating genius of Vieta alone. His skill so disconcerted the Spanish councils for two years, that they published it at Rome, and other parts of Europe, that the French king had only discovered their ciphers by means of magic.

VINTAIN, a town, situated about two miles up a creek on the southern side of the river Gambia. It is much resorted to by Europeans, on account of the great quantities of bees-wax which are brought hither for sale. The wax is collected in the woods by the Feloops, a wild and unsociable race of people. Their country, which is of considerable extent, abounds in rice; and the natives supply the traders, both on the Gambia and Cassamansa rivers, with that article, and also with goats and poultry, on very reasonable terms. The honey which they collect is chiefly used by themselves in making a strong intoxicating liquor, much the same as the mead which is produced from honey in Great Britain.

In their traffic with Europeans, the Feloops generally employ a factor, or agent, of the Mandingo nation, who speaks a little English, and is acquainted with the trade of the river. This broker makes the bargain; and, with the connivance of the European, receives a certain part only of the payment; which he gives to his employer as the whole; the remainder (which is very truly called the *cheating money*) he receives when the Feloop is gone and appropriates to himself as a reward for his trouble. Vintain, according to Mr Park, from whose valuable travels this account of the Feloops is taken, is situated in 13° 9′ North Lat. and 15° 56′ Long West from Greenwich.

VIRGINITY, the test or criterion of a virgin; or that which intitles her to the denomination. See Hymen, *Encycl.*

VISION. In the article Optics, n° 154. (*Encycl.*), it is said, that as we have a power of contracting or relaxing the *ligamenta ciliaria*, and thereby altering the form of the crystalline humour of the eye, we hence see objects distinctly at different distances. It appears, however, from some experiments made by Mr Everard Home and Mr Ramsden, in the year 1794, that this power of contracting and relaxing the ligamenta ciliaris is not alone sufficient to account for the phenomenon. Conversing with Mr Home on the different uses of the chrystalline humour, Mr Ramsden said, that as that humour "consists of a substance of different densities, the central parts being the most compact, and from thence diminishing in density gradually in every direction, approaching the vitreous humour on one side, and the aqueous humour on the other, its refractive power becomes nearly the same with that of the two contiguous substances. That some philosophers have stated the use of the crystalline humour to be, for accommodating

commodating the eye to see objects at different distances; but the firmness of the central part, and the very small difference between its refractive power near the circumference and that of the vitreous or the aqueous humour, seemed to render it unfit for that purpose; its principal use rather appearing to be for correcting the aberration arising from the spherical figure of the cornea, where the principal part of the refraction takes place, producing the same effect that, in an achromatic object-glass, we obtain in a less perfect manner by proportioning the radii of curvature of the different lenses. In the eye the correction seems perfect, which in the object-glass can only be an approximation; the contrary aberrations of the lenses not having the same ratio: so that, if this aberration be perfectly corrected, at any given distance from the centre, in every other it must be in some degree imperfect.

"Pursuing the same comparison: In the achromatic object-glass we may conceive how much an object must appear fainter from the great quantity of light lost by reflection at the surfaces of the different lenses, there being as many primary reflections as there are surfaces; and it would be fortunate if this reflected light was totally lost. Part of it is again reflected towards the eye by the interior surfaces of the lenses; which, by diluting the image formed in the focus of the object-glass, makes that image appear far less bright than it would otherwise have done, producing that milky appearance so often complained of in viewing lucid objects through this sort of telescope.

"In the eye, the same properties that obviate this defect, serve also to correct the errors from the spherical figure, by a regular diminution of density, from the centre of the crystalline outward. Every appearance shews the crystalline to consist of laminæ of different densities; and if we examine the junction of different media, having a very small difference of refraction, we shall find that we may have a sensible refraction without reflection. Now, if the difference between the contiguous media in the eye, or the laminæ in the crystalline, be very small, we shall have refraction without having reflection; and this appears to be the state of the eye; for although we have two surfaces of the aqueous, two of the crystalline, and two of the vitreous humour, yet we have only one reflected image; and that being from the anterior surface of the cornea, there can be no surface to reflect it back, and dilute an image on the retina.

"This hypothesis may be put to the test whenever accident shall furnish us with a subject having the crystalline extracted from one eye, the other remaining perfect in its natural state; at the same time we may ascertain whether or no the crystalline is that part of the organ which serves for viewing objects at different distances distinctly. Seeing no reflection at the surface of the crystalline, might lead some persons to infer that its refractive power is very inconsiderable; but many circumstances shew the contrary: yet what it really is may be readily ascertained by having the focal length and distance of a lens from the operated eye, that enables it to see objects the most distinctly; also the focal length of a lens, and its distance from the perfect eye, that enables it to see objects at the same distance as the perfect eye: these data will be sufficient whereby to calculate the refractive power of the crystalline with considerable precision.

"Again, having the spherical aberration of the different humours of the eye, and having ascertained the refractive power of the crystalline, we have data from whence to determine the proportional increase of its density as it approaches the central part, on a supposition that this property corrects the aberration.

"An opportunity presented itself for bringing the observations of Mr Ramsden, respecting the use of the crystalline lens, to the proof. A young man came into St George's Hospital with a cataract in the right eye. The crystalline lens was readily extracted, and the union of the wound in the cornea took place unattended by inflammation; so that the eye suffered the smallest degree of injury that can attend so severe an operation. The man himself was in health, 21 years had been intelligent, and his left eye perfect: the other and 27 days after commonly short time in a diseased state, from every other defect but operation appeared to be free lens. ...ss of the crystalline

"A number of experiments were made ... perfect eye, assisted by a lens, and compared with imperfect eye. The aim of these trials, which were judiciously varied, was to ascertain whether the eye which had been deprived of the crystalline lens was capable of adjusting itself to distinct vision at different distances. Among other results, the perfect eye, with a glass of $6\frac{1}{8}$ inches focus, had distinct vision at 3 inches; the near limit was $1\frac{7}{8}$ inch, the distant limit less than 7 inches. The imperfect eye, with a glass $2\frac{2}{10}$ inches focus, with an aperture $\frac{1}{10}$ths of an inch, had distinct vision at $2\frac{7}{8}$ inches, the near limit $1\frac{7}{8}$ inch, and the distant limit 7 inches. The accuracy with which the eye was brought to the same point, on repeating the experiment, proved it to be uncommonly correct; and as he did not himself see the scale used for admeasurement, there could be no source of fallacy. From the result of this experiment, it appears that the range of adjustment of the imperfect eye, when the two eyes were made to see at nearly the same focal distance, exceeded that of the perfect eye. Mr Ramsden suggested a reason why the point of distinct vision of the imperfect eye might appear to the man himself nearer than it was in reality; namely, that from the imperfection of this organ he might find it easier to read the letters when they subtended a greater angle than at his real point of distinct vision. The experiments, however, appear to shew that the internal power of the eye, by which it is adjusted to see at different distances, does not reside in the crystalline lens, at least not altogether; and that if any agency in this respect can be proved to reside in the crystalline, the other powers, whatever they may be, are capable of exertion beyond their usual limits, so as to perform its office in this respect.

"From these considerations, and in consequence of other reflections tending to shew that an elongation of the optical axis is not probably the means of adjustment, these philosophers directed their enquiries to ascertain how far the curvature of the cornea might be subject to change. They found by trial that this part of the organ possesses a degree of elasticity which is very considerable, both for its perfection and its range; and by anatomical

Viſion. anatomical diſſection it was found that the four ſtraight muſcles of the eye do in effect terminate in the cornea at their tendinous extremities; that the whole external lamina of the cornea could by gentle force be ſeparated, by means of theſe muſcles, from the eye; ſo that the tendons ſeem loſt in the cornea, and this laſt has the appearance of a central tendon. It was alſo ſeen that the central part of the cornea is the thickeſt and the moſt elaſtic.

"Theſe were conſiderable advances towards eſtabliſhing the hypotheſis of adjuſtment by the external curve of the eye. It remained to be ſhewn, by experiments on the living ſubject, that this curve does really vary in the due direction, when the mind perceives the diſtinct viſible ſenſation of objects at different diſtances. For this purpoſe Mr Ramſden provided an apparatus, conſiſting of a thick board ſteadily fixed, in which was ... ; the ſquare hole large enough to admit a perſon's upper and lower forehead and chin reſting against either of the ſides; ſo that bars, and the cheek protruded, the head was ſteadily when the ...ng on three ſides; and in this poſition the fixed eye projected beyond the outer ſurface of the board. A microſcope, properly mounted, ſo as with eaſe to be ſet in every requiſite poſition, was applied to view the cornea with a magnifying power of thirty times. In this ſituation, the perſon whoſe eye was the object of experiment was deſired to look at the corner of a chimney, at the diſtance of 235 yards, through a ſmall hole in a braſs plate, fixed for that purpoſe, and afterwards to look at the edge of the hole itſelf, which was only ſix inches diſtant. After ſome management and caution, which the delicate nature of theſe experiments requires, the motion of the cornea, which was immediately perceptible, became very diſtinct and certain. The circular ſection of its ſurface remained in a line with the wire in the field of the microſcope, when the eye was adjuſted to the diſtant object, but projected conſiderably beyond it when adapted to the near one. When the diſtant object was only 90 feet from the obſerver, and the near object ſix inches, the difference in the prominence of the cornea was eſtimated at 1-800th of an inch. Theſe experiments were repeated and varied at different times and on different ſubjects. The obſerver at the microſcope found no difficulty in determining, from the appearance of the cornea, whether the eye was fixed on the remote or the near object.

"From theſe different experiments Mr Home conſiders the following facts to have been aſcertained:

"1 That the eye has a power of adjuſting itſelf to different diſtances when deprived of the cryſtalline lens; and therefore the fibrous and laminated ſtructure of that lens is not intended to alter its form, but to prevent reflections in the paſſage of the rays through the ſurfaces of media of different denſities, and to correct ſpherical aberration.

"2 That the cornea is made up of laminæ; that it is elaſtic, and when ſtretched is capable of being elongated 1 11th part of its diameter, contracting to its former length immediately upon being left to itſelf.

"3. That the tendons of the four ſtraight muſcles of the eye are continued on to the edge of the cornea, and terminate, or are inſerted, in its external laminæ: their action will therefore extend to the edge of the cornea.

"4. That in changing the focus of the eye from ſeeing with parallel rays to a near diſtance, there is a viſible alteration produced in the figure of the cornea, rendering it more convex; and when the eye is again adapted to parallel rays, the alteration by which the cornea is brought back to its former ſtate is equally viſible."

Mr Home made many other experiments with a view to throw light upon this curious ſubject; and the reſult of the whole appears to be, that the adjuſtment of the eye is produced by three different changes in that organ; an increaſe of curvature in the cornea, an elongation of the axis of viſion, and a motion of the cryſtalline lens. Theſe changes, in a great meaſure, depend upon the contraction of the four ſtraight muſcles of the eye. Mr Ramſden, from computations grounded on the principles of optics and general ſtate of the facts, calculates that the increaſe of curvature of the cornea may be capable of producing one-third of the effect, and that the change of place of the lens, and elongation of the axis of viſion, ſufficiently account for the other two thirds of the quantity of adjuſtment neceſſary to make up the whole.

VITALITY, the power of ſubſiſting in life, which the faſhionable philoſophers of the French and German ſchools attribute to *chemiſtry*. For a confutation of their abſurd and impious jargon on this ſubject, we refer our readers, with ſome degree of confidence, to the articles PHYSIOLOGY (*Encycl.*), and *Animal* SUBSTANCES (*Suppl.*)

VIVERRA (ſee *Encycl.*) A new ſpecies of this genus of animals was diſcovered by Vaillant during his laſt travels in Africa; at leaſt he ranks under the generic name *Viverra*, the animal of which he gives the following deſcription. Its body was of the ſize of that of a kitten ſix months old: it had a very large noſe, the upper jaw exceeding the lower near two-thirds of an inch in length, and forming a ſort of moveable ſnout reſembling that of the *conti* of Guiana. The fore feet were armed with four large claws, very ſharp and curved; the hind ones have each five, but they are ſhort and blunt. All the fur on the upper part of the body is marked with croſs bands of a deep brown colour, on a ground of light brown with which many white hairs are intermixed. The lower part of the body and inſides of the legs are of a reddiſh white. The tail, which is very fleſhy, and more than two thirds longer than the body, is black at the tip, and the reſt brown, intermixed with white hairs.

This animal employs its fore paws to dig very deep holes in the earth, in which it remains concealed during the day, not going out till ſun-ſet in queſt of food.

The Hottentots who accompanied our traveller called it *muys-hond* (a mouſe dog); a general name among the inhabitants of the Cape for all the ſmaller carnivorous quadrupeds.

VIVES (Ludovicus), the contemporary and friend of Eraſmus, was a native of Valentia in Spain. Though well trained in all the ſubtleties of the ſcholaſtic philoſophy at Paris, he had the good ſenſe to diſcover its futility, and diligently applied himſelf to more uſeful ſtudies. At Louvain he undertook the office of a preceptor, and exerted himſelf with great ability and ſucceſs in correcting barbariſm, chaſtiſing the corrupters of learning, and reviving a taſte for true ſcience and elegant letters. Eraſmus, with whom he lived upon the footing

Vives, Ultramarine.

footing of intimate friendſhip, ſpeaking of Vives when he was only 26 years of age, ſays, that there was no part of philoſophy in which he did not excel; and that he had made ſuch proficiency in learning, and in the arts of ſpeaking and writing, that he ſcarcely knew his equal. He wrote a commentary upon Auguſtine's treatiſe *De Civitate Dei*, which diſcovers an extenſive acquaintance with ancient philoſophy. Henry VIII. of England, to whom he dedicated this work, was ſo pleaſed with it, that he invited the author to his court, and made him preceptor to his daughter Mary. Though he diſcharged his office with great fidelity, yet in conſequence of his oppoſition to the king's divorce, he fell under his diſpleaſure; and it was not without difficulty that he eſcaped to Bruges, where he devoted the remainder of his days to ſtudy. He died in the year 1537, or, according to Thuanus, in 1541. With Eraſmus and Buddæus he formed a triumvirate of literature which did honour to the age. He wrote *De Prima Philoſophia*, "On the Firſt Philoſophy;" *De Explanatione Eſſentiarum*, "On the Explanation of Eſſences;" *De Cenſura Veri*, "On the Teſt of Truth;" *De Initiis, Sectis, et Laudibus Philoſophiæ*, "On the Origin, Sects, and Praiſes of Philoſophy;" and *De Corruptis Artibus et Tradendis Diſciplinis*, "On the Corruption of Science, and on Education." Theſe writings, of which the two laſt are the moſt valuable, diſcover great ſtrength of judgment, an extenſive knowledge of philoſophy, much enlargement of conception, uncommon ſagacity in detecting the errors of ancient and modern philoſophers, particularly of Ariſtotle and his followers, and, in fine, a mind capable of attempting things beyond the ſtandard of the age in which he lived. To all this he added great perſpicuity and elegance of ſtyle, not unworthy of the friend of Eraſmus.

ULTRAMARINE is a very fine blue powder, almoſt of the colour of the corn flower or blue bottle, which has this uncommon property, that, when expoſed to the air or a moderate heat, it neither fades nor becomes tarniſhed. On this account it is uſed in painting; but it was employed formerly for that purpoſe much more than at preſent, as ſmalt, a far cheaper article, was not then known. (See COBALT, in this *Suppl.*) Ultramarine is made of the blue parts of the lapis lazuli, by ſeparating them as much as poſſible from the other coloured particles with which they are mixed, and reducing them to a fine powder. The real lapis lazuli is found in the mountains of that part of Tartary called Bucharia, which extends eaſtwards from the Caſpian ſea, and particularly at Kalab and Budukſchu. It is ſent thence to the Eaſt Indies, and from the Eaſt Indies to Europe. Good ultramarine muſt be of a beautiful dark colour, and free from ſand as well as every other mixture. It muſt unite readily with oil; it muſt not become tarniſhed on a red-hot tile or plate of iron, and it ought to diſſolve in ſtrong acids, almoſt like the zeolite, without cauſing an efferveſcence. In the year 1763, an ounce of it at Paris coſt four pounds ſterling, and an ounce of *cendre d'outremer*, which is the refuſe, two pounds. The baſis of this colour was long ſuſpected to be copper. but the experiments of Margraff ſhewed that it was iron, in ſome unknown ſtate of combination. New light has been thrown on this ſubject by Morveau, who has diſcovered that ſelenite mixed with iron, when decompoſed by carbonaceous matter, yields a blue ſulphuret of iron of equal permanency with the true ultramarine.

At preſent, ſmalt of a good colour is often purchaſed at a dear rate and ſubſtituted for ultramarine: and it is found that the colour of this preparation of cobalt is more durable in the fire than even that of the lapis lazuli For the analyſis of lapis lazuli, ſee MINERALOGY, n° 69. *Suppl.*

Vortices.

VORTICES of Des Cartes are now juſtly exploded; but being the fiction of a very ſuperior mind, they are ſtill an object of curioſity as being the foundation of a great philoſophical romance. According to the author of that romance, the whole of infinite ſpace was full of matter; for with him matter and extenſion were the ſame, and conſequently there could be no void. This immenſity of matter he ſuppoſed to be divided into an infinite number of very ſmall cubes; all of which, being whirled about upon their own centres, neceſſarily gave occaſion to the production of two different elements. The firſt conſiſted of the angular parts which, having been neceſſarily rubbed off, by their mutual friction, conſtituted a yet ſmaller and moveable part of matter. The ſecond conſiſted of thoſe little globules that were formed by the rubbing off of the firſt. The interſtices betwixt theſe globules of the ſecond element were filled up by the particles of the firſt. But in the infinite colliſions, which muſt occur in an infinite ſpace filled with matter, and all in motion, it muſt neceſſarily happen that many of the globules of the ſecond element ſhould be broken and grinded down into the firſt. The quantity of the firſt element having thus been increaſed beyond what was ſufficient to fill up the interſtices of the ſecond, it muſt, in many places, have been heaped up together, without any mixture of the ſecond along with it. Such, according to Des Cartes, was the original diviſion of matter. Upon this infinitude of matter thus divided, a certain quantity of motion was originally impreſſed by the Creator of all things, and the laws of motion were ſo adjuſted as always to preſerve the ſame quantity in it, without increaſe, and without diminution. Whatever motion was loſt by one part of matter, was communicated to ſome other; and whatever was acquired by one part of matter, was derived from ſome other: and thus, through an eternal revolution from reſt to motion, and from motion to reſt, in every part of the univerſe, the quantity of motion in the whole was always the ſame.

But as there was no void, no one part of matter could be moved without thruſting ſome other out of its place, nor that without thruſting ſome other, and ſo on. To avoid, therefore, an infinite progreſs, he ſuppoſed that the matter which any body puſhed before it rolled immediately backwards to ſupply the place of that matter which flowed in behind it; as we may obſerve in the ſwimming of a fiſh, that the water which it puſhes before it immediately rolls backwards to ſupply the place of what flows in behind it, and thus forms a ſmall circle or vortex round the body of the fiſh. It was in the ſame manner that the motion originally impreſſed by the Creator upon the infinitude of matter neceſſarily produced in it an infinity of greater and ſmaller vortices, or circular ſtreams: and the law of motion being ſo adjuſted as always to preſerve the ſame quantity of motion in the univerſe, thoſe vortices either continued

for ever, or by their dissolution gave birth to others of the same kind. There was thus at all times an infinite number of greater and smaller vortices, or circular streams, revolving in the universe.

But whatever moves in a circle is constantly endeavouring to fly off from the centre of its revolution. For the natural motion of all bodies is in a straight line. All the particles of matter therefore, in each of those greater vortices, were continually pressing from the centre to the circumference, with more or less force, according to the different degrees of their bulk and solidity. The larger and more solid globules of the second element forced themselves upwards to the circumference, while the smaller, more yielding, and more active particles of the first, which could flow even through the interstices of the second, were forced downwards to the centre. They were forced downwards to the centre notwithstanding [illegible] their natural tendency was upwards to the [illegible] wood, when ference; for the same reason [illegible] upwards to the surface, notplunged in water, [illegible] natural tendency is downwards to the withstanding [illegible] because its tendency downwards is less strong than that of the particles of water, which, therefore, if one may say so, press in before it, and thus force it upwards. But there being a greater quantity of the first element than what was necessary to fill up the interstices of the second, it was necessarily accumulated in the centre of each of these great circular streams, and formed there the fiery and active substance of the sun. For, according to that philosopher, the solar systems were infinite in number, each fixed star being the centre of one; and he is among the first of the moderns who thus took away the boundaries of the universe: even Copernicus and Kepler, themselves, have confined it within what they supposed the vault of the firmament.

The centre of each vortex being thus occupied by the most active and moveable parts of matter, there was necessarily among them a more violent agitation than in any other part of the vortex, and this violent agitation of the centre cherished and supported the movement of the whole. But among the particles of the first element, which fill up the interstices of the second, there are many, which, from the pressure of the globules on all sides of them, necessarily receive an angular form, and thus constitute a third element of particles less fit for motion than those of the other two. As the particles, however, of this third element were formed in the interstices of the second, they are necessarily smaller than those of the second, and are therefore, along with those of the first, urged down towards the centre, where, when a number of them happen to take hold of one another, they form such spots upon the surface of the accumulated particles of the first element, as are often discovered by telescopes upon the face of that sun which enlightens and animates our particular system. Those spots are often broken and dispelled by the violent agitation of the particles of the first element, as has hitherto happily been the case with those which have successively been formed upon the face of our sun. Sometimes, however, they encrust the whole surface of that fire which is accumulated in the centre; and the communication betwixt the most active and the most inert parts of the vortex being thus interrupted, the rapidity of its motion immediately begins to languish, and can no longer defend it from being swallowed up and carried away by the superior violence of some other like circular stream; and, in this manner, what was once a sun becomes a planet. Thus the time was, according to the system, when the Moon was a body of the same kind with the sun, the fiery centre of a circular stream of ether, which flowed continually round her; but her face having been crusted over by a congeries of angular particles, the motion of this circular stream began to languish, and could no longer defend itself from being absorbed by the more violent vortex of the earth, which was then, too, a sun, and which chanced to be placed in its neighbourhood. The moon therefore became a planet, and revolved round the earth. In process of time, the same fortune, which had thus befallen the moon, befel also the earth [illegible] face was encrusted by a gross and ina[illegible] substance; the motion of its vortex [illegible] to languish, and it was absorbed by the greater vortex of the sun: but though the vortex of the earth had thus become languid, it still had force enough to occasion both the diurnal revolution of the earth, and the monthly motion of the moon. For a small circular stream may easily be conceived as flowing round the body of the earth, at the same time that it is carried along by that great ocean of ether which is continually revolving round the sun; in the same manner, as in a great whirlpool of water, one may often see several small whirlpools, which revolve round centres of their own, and at the same time are carried round the centre of the great one. Such was the cause of the original formation and consequent motions of the planetary system. When a solid body is turned round its centre, those parts of it which are nearest, and those which are remotest from the centre, complete their revolutions in one and the same time. But it is otherwise with the revolutions of a fluid: the parts of it which are nearest the centre complete their revolutions in a shorter time than those which are remoter. The planets, therefore, all floating in that immense tide of æther which is continually setting in from west to east round the body of the sun, complete their revolutions in a longer or a shorter time, according to their nearness or distance from him.

This bold system was eminently fitted to captivate the imagination; and though fraught with contradictions and impossibilities, attempts have been made to revive it, even in this country, under different names. All those systems which represent the motions of the heavenly bodies as being the effect of the physical agency of æthers, of air, of fire, and of light, of which the universe is conceived to be full, labour under the same difficulties with the Cartesian hypothesis; and very few of them, if any, are so neatly put together. It is surely sufficient, however, to demolish this goodly fabric, barely to ask how an absolute infinity of matter can be divided into cubes, or any thing else? how there can possibly be interstices in a perfect plenum? or how in such a plenum any portion of matter can be thrust from its place?

URALIAN Cossacs, a people that inhabit the Russian province of Orenburg in Asia, on the south side of the river Ural. These Cossacs are descended from those of the Don: they are a very valiant race. They profess the Greek religion; but there is a kind of dissenters from the established religion, whom the Russians called *Roskolniki*, or Separatists, and who style themselves *Staroverski*, or Old Believers. They consider

der the service of the established church as profane and sacrilegious, and have their own priests and ceremonies. The Uralian Cossacs are all enthusiasts for the ancient ritual, and prize their beards almost equal to their lives. A Russian officer having ordered a number of Cossac recruits to be publicly shaved in the town of Yaisk, in 1771, this wanton insult excited an insurrection, which was suppressed for a time; but, in 1773, that daring impostor, Pugatchef, having assumed the name and person of Peter III. appeared among them, and taking advantage of this circumstance, and of their religious prejudices, roused them once more into open rebellion. This being at last effectually suppressed by the defeat and execution of the impostor (See SUWOROW, *Suppl.*), in order to extinguish all remembrance of this rebellion, the river Yaik was called *Ural*; the Yaik Cossacs were denominated *Uralian Cossacs*; and the town of Yaitsk, *Uralsk*. The Uralian Cossacs enjoy the right of fishing on the coast of the Caspian Sea, for 47 miles on each side of the river Ural. Their principal fishery is for sturgeons and beluga, whose roe supplies large quantities of caviare; and the fish, which are chiefly salted and dried, afford a considerable article of consumption in the Russian empire. In consequence of these fisheries, these Cossacs are very rich.

URBINO, a town of Italy, in the territory of the Pope, and capital of the duchy of Urbino, with an old citadel, an archbishop's see, and a handsome palace, where the dukes formerly resided. The houses are well built, and great quantities of fine earthen ware are made here. It is seated on a mountain, between the rivers Metro and Foglia, 18 miles south of Rimini, 58 east of Florence, and 120 north-east of Rome. E. Lon. 12. 40. N. lat. 43. 46.

URBINO, a duchy of Italy, in the territory of the church, bounded on the north by the gulph of Venice; on the south, by Perugino and Umbria; on the east, by the marquisate of Ancona; and on the west, by Tuscany and Romagna. It is about 55 miles in length, and 45 in breadth. Here is great plenty of game and fish; but the air is not very wholesome, nor is the soil fertile. Urbino is the capital.

URCEOLA, a lately discovered genus of the *pentandria* class, and *monogynia* order of plants, ranking immediately after TABERNÆ MONTANA (see *Encycl.*), and consequently belonging to the 30th natural order or class called *Contortæ* by Linnæus in his natural method of arrangement. One of the qualities of the plants of this order is their yielding, on being cut, a juice which is generally milky, and for the most part deemed of a poisonous nature. The genus is thus characterised by Dr Roxburgh: *Calyx* beneath five-toothed; corol one petaled, pitcher shaped, with its contracted mouth five toothed: nectary entire, surrounding the germs; follicles two, round, drupacious; seeds numerous, immersed in pulp. There is but one known species, which is thus described by the same eminent botanist;

URCEOLA ELASTICA: Shrubby, twining, leaves opposite, oblong, panicles terminal, is a native of Sumatra, Prince of Wales's Island, &c. Malay countries. *Stem* woody, climbing over trees, &c. to a very great extent, young shoots twining, and a little hairy, bark of the old woody parts thick, dark coloured, considerably uneven, a little scabrous, on which are found several species of moss, particularly large patches of lichen; the wood is white, light, and porous. *Leaves* opposite, short-petioled, horizontal, ovate, oblong, pointed, entire, a little scabrous, with a few scattered white hairs on the under side. *Stipules* none. *Panicle* terminal, brachiate, very ramous. *Flowers* numerous, minute, of a dull greenish colour, and hairy on the outside. *Bracts* lanceolate, one at each division and subdivision of the panicle. *Calyx* perianth, one-leaved, five toothed, permanent. *Corol* one petaled, pitcher shaped, hairy, mouth much contracted, five toothed, divisions erect, acute, nectary entire, cylindric, embracing the lower two-thirds of the germs. *Stamens*, filaments five, very short from the base of the corol. Anthers arrow shaped, converging, bearing their pollen in two grooves on the inside, near the apex; between these grooves and the insertions of the filaments they are covered with white soft ... *Pistil*, germs two; above the nectary they are very hairy ... tops. Style single, short; the margins of their truncated ... ovate, with a circular band, dividing it into ... Stigma ... portions of different colours. *Per.* Follicles two, ... laterally compressed into the shape of a kidney, wrinkled, leathery, about three inches in their greatest diameters—one celled, two valved. *Seeds* very numerous, reniform, immersed in firm fleshy pulp.

See Plate XLVII. where fig. 1. is a branchlet in flower of the natural size. 2. A flower magnified. 3. The same laid open, which exposes to view the situation of the stamens inserted into the bottom of the corol, the nectarium surrounding the lower half of the two germs, their upper half with hairy margins, the style and ovate party coloured; stigma appearing above the nectary. 4. Outside of one of the stamens; and, 5. Inside of the same, both much magnified. 6. The nectarium laid open, exposing to view the whole of the pistil. 7. The two seed vessels (called by Linnæus *folliclus*), natural size; half of one of them is removed, to shew the seed immersed in pulp. A portion thereof is also cut away, which more clearly shews the ... and shape of the seed.

From wounds made in the bark of this plant there oozes a milky fluid, which on exposure to the open air separates into an elastic coagulum, and watery liquid, apparently of no use, after the separation takes place. This coagulum is not only like the American caoutchouc or Indian rubber, but possesses the same properties; for which, see CAOUTCHOUC, both in the *Encycl.* and *Suppl.*

The chemical properties of this vegetable milk, while fresh, were found by Mr Howison, late surgeon on Prince of Wales's Island, surprisingly to resemble those of animal milk. From its decomposition, in consequence of spontaneous fermentation, or by the addition of acids, a separation takes place between its caseous and serous parts, both of which are very similar to those produced by the same processes from animal milk. An oily or butyrous matter is also one of its component parts, which appears upon the surface of the gum so soon as the latter has attained its solid form. He endeavoured to form an extract of this milk so as to approach to the consistence of new butter, by which he hoped to retard its fermentative stage, without depriving it of its useful qualities; but as he had no apparatus for distilling, the surface of the milk, that was exposed to the air, instantly formed into a solid coat, by which

Urinary, Urtica.

which the evaporation was in a great degree prevented. He, however, learned, by collecting the thickened milk from the inſide of the coats, and depoſiting it in a jelly pot, that, if excluded from the air, it might be preſerved in this ſtate for a conſiderable length of time; and even without any preparation he kept it in bottles, tolerably good, upwards of twelve months.

URINARY concretions. See *Animal Substances*, Suppl.

URTICA. See *Encycl.* where it is obſerved that the common nettle, though it has a place in the *materia medica*, is now very little uſed. It has lately been recommended, however, by *Zannetini*, a phyſician who attended the French army in Italy, as a good ſubſtitute in fevers for cinchona. The ſucceſs of ſome experiments, which he made with it in tertian and quartan ... ſanguine malignant fevers, ſurpaſſed, he ſays, his expectation. The nettle ... duces a ſpeedier effect than bark for it heats in a great degree, and when the doſe is pretty ſtrong, occaſions a lethargic ſleep. The doſe muſt never exceed a dram, and is given in wine two or three times in the courſe of 24 hours. Zannetini found this medicine of great ſervice to guard againſt that total exhauſtion which forms the principal character of malignant fevers; and he recommends a ſlight infuſion of it in wine as an excellent preſervative for thoſe who reſide in marſhy and inſalubrious diſtricts. In employing the nettle in fever, Zannetini gives the ſame caution as ought to be obſerved in regard to cinchona, that is, that it muſt not be employed where there is an inclination to inflammation, or where a continued fever, ariſing from obſtructions, exiſts. This diſcovery is not unworthy the attention of phyſicians, and de... leaſt to be farther inveſtigated, as a great deal would be ſaved if cinchona could be entirely diſpenſed with.

W.

Wales.

WALES, New South, is a country which muſt be intereſting on account of the ſingular colony which was ſettled there in the year 1788. Under the title *New Holland* (*Encycl.*) ſome account has been given of that ſettlement, as well as of the climate and the ſoil about Port Jackſon; but it will probably gratify the curioſity of our readers, if we give a ſhort hiſtory of thoſe European ſettlers, of whom it is to be hoped that they carried not with them, to that diſtant ſhore,

"Minds not to be changed by time or place."

This hiſtory we ſhall take from the accurate *Account of the Engliſh Colony in New South Wales*, by David Collins, Eſq; who went out with Governor Phillip, and continued to execute the offices of Judge-advocate and Secretary till the cloſe of the year 1796; and we ſhall begin our narrative from the diſembarkation of the firſt coloniſts, when his Majeſty's commiſſion to the governor, and the letters patent eſtabliſhing courts of criminal and civil judicature in the territory were read.

The criminal court was conſtituted a court of record, and was to conſiſt of the judge-advocate and ſuch ſix officers of the ſea and land ſervice as the governor ſhall, by precept iſſued under his hand and ſeal, require to aſſemble for that purpoſe This court has power to inquire of, hear, determine, and puniſh all treaſons, miſpriſions of treaſons, murders, felonies, forgeries, perjuries, treſpaſſes, and other crimes whatſoever that may be committed in the colony; the puniſhment for ſuch offences to be inflicted according to the laws of England as nearly as may be, conſidering and allowing for the circumſtances and ſituation of the ſettlement and its inhabitants. The charge againſt any offender is to be reduced into writing, and exhibited by the judge-advocate: witneſſes are to be examined upon oath, as well for as againſt the priſoner; and the court is to adjudge whether he is guilty or not guilty by the opinion of the major part of the court. If guilty, and the offence is capital, they are to pronounce judgment of death, in like manner as if the priſoner had been convicted by the verdict of a jury in England, or of ſuch corporal puniſhment as the court, or the major part of it, ſhall deem meet. And in caſes not capital, they are to adjudge ſuch corporal puniſhment as the majority of the court ſhall determine. But no offender is to ſuffer death unleſs five members of the court ſhall concur in adjudging him to be guilty, until the proceedings ſhall have been tranſmitted to England, and the king's pleaſure ſignified thereupon. The provoſt-marſhall is to cauſe the judgement of the court to be executed according to the governor's warrant under his hand and ſeal.

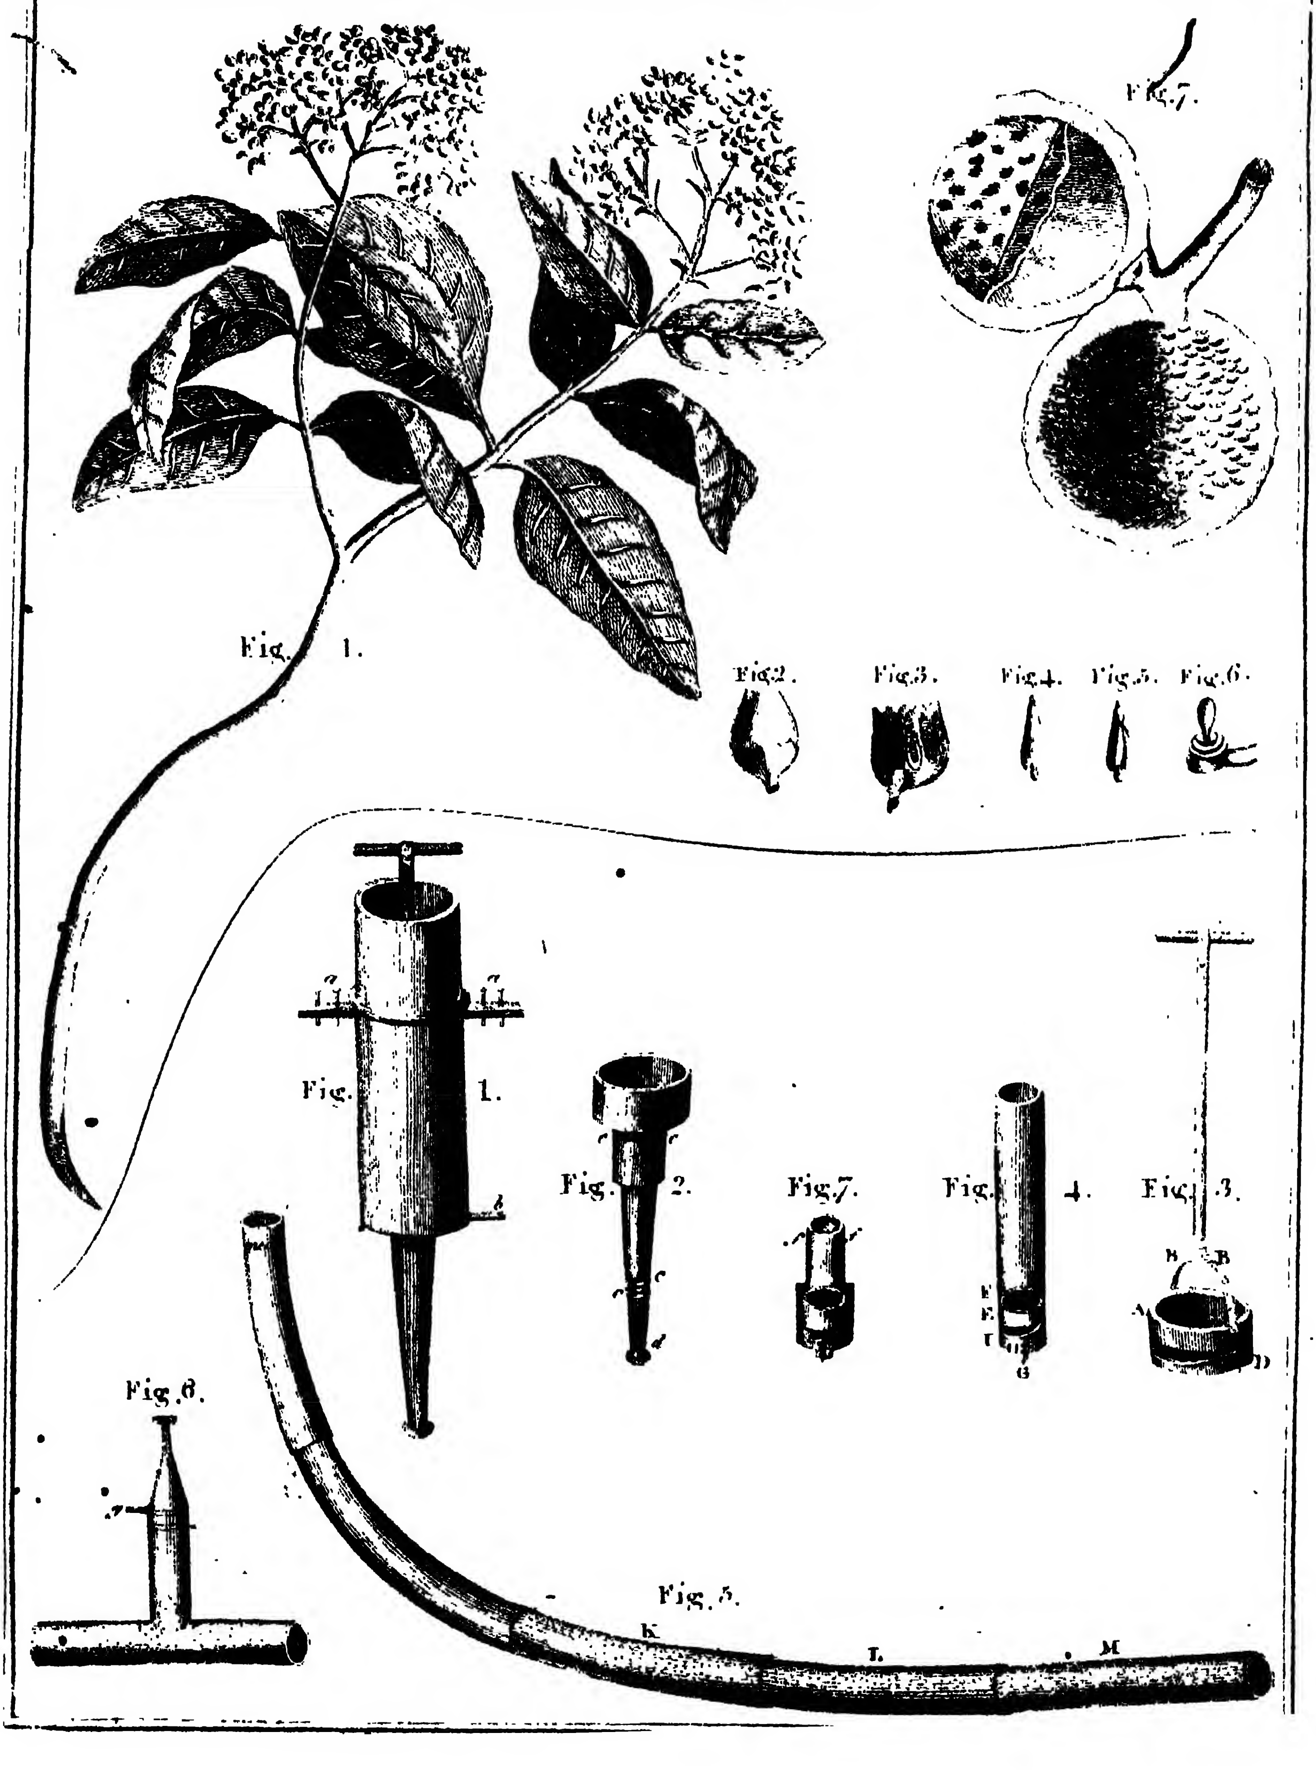
Beſide this court for the trial of criminal offenders, there is a civil court, conſiſting of the judge-advocate and two inhabitants of the ſettlement, who are to be appointed by the governor; which court has full power to hear and determine in a ſummary way all pleas of lands, houſes, debts, contracts, and all perſonal pleas whatſoever.

From this court, on either party, plaintiff or defendant, finding himſelf or themſelves aggrieved by the judgment or decree, an appeal lies to the governor, and from him, where the debt or thing in demand ſhall exceed the value of L. 300, to the king in council.

A vice-admiralty court was alſo appointed, for the trial of offences on the high ſeas; and the governor, lieutenant-governor, and judge-advocate, were by patent made juſtices of the peace, with a power in the governor to appoint other juſtices.

The ſituation which Governor Phillip had ſelected for his reſidence, and for the principal ſettlement, was the eaſt ſide of a cove in Port Jackſon, which he called *Sydney Cove*. Its latitude was found to be 33° 52′ 30″ ſouth, and its longitude 152° 19′ 30″ eaſt. This ſituation was choſen without due examination; for it ſoon appeared that the head or upper part of the cove wore a much more favourable appearance than the ground immediately about the ſettlement. From the natives, the new ſettlers met no oppoſition: during the firſt ſix weeks they received only one viſit from them, two men ſtrolling one evening into the camp, and remaining in it

Urceola Elastica. Plate XLII.



it for about half an hour. They appeared to admire whatever they saw; and after receiving a hatchet (of the use of which the eldest instantly and curiously shewed his knowledge, by turning up his foot and sharpening a piece of wood on the sole with the hatchet) took their leave, apparently well pleased with their reception. The fishing boats also frequently reported their having been visited by many of these people when hauling the seine; at which labour they often assisted with cheerfulness, and in return were generally rewarded with a part of the fish taken.

The first labour in which the convicts were employed was that of building huts; and for this purpose it was found necessary to divide them into gangs, and to appoint an overseer to each, who should see that the proper quantity of work was performed. The provisions were distributed by a weekly ration, and to each man were allowed 7lb. of biscuit, 1lb. of flour, 7lb. of beef or 4lb. of pork, 3 pints of pease, and 6 ounces of butter. To the female convicts two thirds of this ration were allowed. This was the full ration, which, in many instances, it became necessary to reduce; and once, in consequence of the delay of transports with a supply, the convicts were put on an allowance of which flesh meat constituted no part.

The temporary huts in which the colonists lived, for some time after their arrival, were formed principally of the cabbage tree. With this the sides and ends were filled; the posts and plates being made of the pine; and the whole was plastered with clay. The roofs were generally thatched with the grass of the gumrush; though some were covered with clay, but several of these failed; the weight of the clay and rain soon destroying them. In a short time they applied themselves to the burning of bricks; by which their habitations soon became much more lasting and comfortable. The progress of the colony, however, towards that degree of convenience which was within its reach, was greatly impeded by the incorrigible vices of those who principally composed it. Drunkenness, theft, robbery, and unconquerable laziness, continued to mark the character of the great body of the convicts. Though to fly from the colony, and venture into the interior of the country, was inevitable death in the form of famine or of murder, yet such was the invincible antipathy to labour manifested by some of those people, that they often fled to the woods, from which they seldom returned; some dying of hunger, and some being sacrificed by the natives. Disinclination to labour produced here, as elsewhere, its natural effect—robbery

In the month of May 1788, a lad of 17 years of age was tried, convicted, and executed, for breaking open a tent belonging to one of the transport ships; several others were taken into custody in that month for various thefts and burglaries, and two were afterward tried and executed. One of these had absconded, and lived in the woods for 19 days, subsisting by what he was able to procure by nocturnal depredations among the huts and stock of individuals. His visits for this purpose were so frequent and daring, that it became absolutely necessary to proclaim him an outlaw. By the negligence of one of those fellows who had been entrusted with the care of the cattle, the bull and four cows were lost: he left them in the fields, and returned to his hut to dine; and in the mean time they either strayed away or were driven off by the natives. Five years elapsed before these cattle were discovered wild, at a considerable distance up the country, and greatly multiplied.

The perpetration of crimes, chiefly theft and robbery, had become so prevalent before twenty months had passed since the colony was established, that it was necessary to think of a system of police. A plan was presented to the governor by a *convict*, which with some improvements was adopted on the 8th of August 1789. The following are the heads of the arrangement.

The settlement was divided into four districts, over each of which was placed a watch consisting of three persons, one principal and two subordinate watchmen. These being selected from among those convicts whose conduct and character had been unexceptionable since their landing, were vested with authority to patrole at all hours in the night, to visit such places as might be deemed requisite for the discovery of any felony, trespass, or misdemeanor, and to secure for examination all persons that might appear to be concerned therein; for which purpose they were directed to enter any suspected hut or dwelling, or to use any other means that might appear expedient. They were required to detain and give information to the nearest guardhouse of any soldier or seaman who should be found straggling after the tattoo had been beat. They were to use their utmost endeavours to trace out offenders on receiving accounts of any depredation; and in addition to their night-duty, they were directed to take cognizance of such convicts as gamed, or sold or bartered their slops or provisions, and report them for punishment. A return of all occurrences during the night was to be made to the judge-advocate; and the military were required to furnish the watch with any assistance they might be in need of, beyond what the civil power could give them. They were provided each with a short staff, to distinguish them during the night, and to denote their office in the colony; and were instructed not to receive any stipulated encouragement or reward from any individual for the conviction of offenders, but to expect that negligence or misconduct in the execution of their trust would be punished with the utmost rigour. It was to have been wished, says Mr Collins, that a watch established for the preservation of public and private property had been formed of free people, and that necessity had not compelled us, in selecting the first members of our little police, to appoint them from a body of men, in whose eyes, it could not be denied, the property of individuals had never before been sacred But there was not any choice: The military had their line of duty marked out for them, and between them and the convict there was no description of people from whom overseers or watchmen could be provided. It might, however, be supposed, that among the convicts there must be many who would feel a pride in being distinguished from their fellows, and a pride that might give birth to a returning principle of honesty. It was hoped that the convicts whom we had chosen were of this description; some effort had become necessary to detect the various offenders who were prowling about with security under cover of the night; and the convicts who had any property were themselves interested in defeating such practices. They promised fidelity and diligence, from which the scorn of their fellow-prisoners should not induce them to swerve, and began with a cou-

confidence of fuch as the duty which they had themfelves offered to undertake.

A fpecies of difturber now infefted the colony, againft which the vigilance of a police could not guard. Rats, in immenfe numbers, had attacked the provifion ftores, and could be counteracted only by removing the provifions from one ftore to another. When their ravages were firft difcovered, it was found that eight cafks of flour were already deftroyed by thefe vermin. Such of thefe animals as efcaped the dogs, which were fet upon them, flew to the gardens of individuals, where they rioted on the Indian corn that was growing, and did confiderable mifchief.

Our author gives the moft melancholy account of the extreme fufferings of the early coloniits from want of provifions, and of the difeafes imported into the country by newcomers, who had either caught them on the voyage or brought them from England. The fettlers on *Norfolk Ifland* (fee *Encycl.*), to which New South Wales was a mother country, muft have been much more liable than that colony to fuffer from famine, had they not fometimes obtained a temporary fupply from a fource which was unknown at Sydney Cove. On a mountain in the ifland, to which had been given the name of *Mount Pitt*, they were fortunate enough to obtain, in an abundance almoft incredible, a fpecies of aquatic birds, anfwering the defcription of that known by the name of the *puffin*. Thefe birds came in from the fea every evening, in clouds literally darkening the air, and defcending on Mount Pitt, depofited their eggs in deep holes made by themfelves in the ground, generally quitting them in the morning, and returning to feek their fubfiftence in the fea. From two to three thoufand of thefe birds were often taken in a night. Their feeking their food in the ocean left no doubt of their own flefh partaking of the quality of that upon which they fed; but to people circumftanced as were the inhabitants on Norfolk Ifland, this leffened not their importance; and while any Mount Pitt birds (fuch being the name given them) were to be had, they were eagerly fought.

The firft fettler in New South Wales, who declared himfelf able to live on the produce of his farm, without any affiftance from the ftores, was James Rufe; who in April 179· relinquifhed his claim to any farther fhare of the public provifion. As a reward, the governor immediately put him in poffeffion of an allotment of 30 acres.

In the July of the fame year, the convicts whofe terms of tranfportation had expired were now collected, and by the authority of the governor informed, that fuch of them as wifhed to become fettlers in this country fhould receive every encouragement; that thofe who did not, were to labour for their provifions, ftipulating to work for 12 or 18 months certain: and that in the way of fuch as preferred returning to England no obftacles would be thrown, provided they could procure paffages from the mafters of fuch fhips as might arrive; but that they were not to expect any affiftance on the part of government to that end. The wifh to return to their friends appeared to be the prevailing idea, a few only giving in their names as fettlers, and none engaging to work for a certain time.

That the wifh to return home was ftrong indeed, and paramount to all other feelings, was evinced in a very melancholy inftance fome time before. A convict, an elderly man, was found dead in the woods, near the fettlement; who, on being opened, it appeared, had died from want of nourifhment; and it was found that he was accuftomed to deny himfelf even what was abfolutely neceffary to his exiftence, abftaining from his provifions, and felling them for money, which he was referving, and had fomewhere concealed, in order to purchafe his paffage to England when his time fhould terminate!

Of fome convicts whofe terms of tranfportation had expired, the governor eftablifhed a new fettlement in Auguft 1791, at a place which he called *Profpect Hill*, about twenty miles diftant from Sydney Cove; and another refidence was formed at the Ponds within three or four miles of the former. This made the fourth fettlement in the colony, exclufively of that at Norfolk Ifland.

About this time the governor received from England a public feal for the colony: on the obverfe of which were the king's arms and royal titles; and on the reverfe, emblematic figures fuited to the fituation of the people for whofe ufe it was defigned. The motto was "*Sic fortis Etruria crevit;*" and in the margin were the words "*Sigillum Nov. Camb. Auft.*" A commiffion alfo arrived, empowering him to remit abfolutely, or conditionally, the whole or any part of the term for which the felons fent to the colony might be tranfported. By this power he was enabled to beftow on fuperior honefty and induftry the moft valuable reward which, in fuch circumftances, they could receive.

In addition to the calamities under which the fettlement had fo often laboured from being reduced to very fhort allowance of provifions, and the frequency of the ordinary difeafes which were to be expected among a people fo fituated, a new malady of a very alarming nature was perceived about April 1792. Several convicts were feized with infanity; and as the major part of thofe who were vifited by this calamity were females, who, on account of their fex, were not haraffed with hard labour, and who in general fhared largely of fuch little comforts as were to be procured in the fettlement, it was difficult to affign a caufe for this diforder. It feems, however, to have been of fhort duration; for we hear not of it again during the period that Mr Collins's narrative comprehends.

About this time (1792) the colony had affumed fomething of an eftablifhed form. Brick huts were in hand for the convicts in room of the miferable hovels occupied by many, which had been put up at their firft landing, and in room of others which, from having been erected on fuch ground as was then cleared, were now found to interfere with the direction of the ftreets which the governor was laying out. People were alfo employed in cutting paling for fencing in their gardens. At a place called Paramatta, about 16 miles from Sydney Cove, fituated on a fmall river which runs into Port Jackfon, the people were employed, during the greateft part of the month of May, in getting in the maize and fowing wheat. A foundation for an hofpital was laid, a houfe built for the mafter carpenter, and roofs prepared for the different huts either building or to be built in future.

In December 1792, when Captain Phillip refigned the government, nearly five years from the foundation of

of the colony, there were in cultivation at the different ſettlements 1429 acres, of which 417 belonged to ſettlers; that is, 67 ſettlers, for there were no more, cultivated nearly half as much ground as was cultivated by the public labour of all the convicts; a ſtriking proof of the ſuperior zeal and diligence with which men exert themſelves when they have an intereſt in their labour. Of free ſettlers, whoſe exertions promiſed ſo fairly to promote the intereſts of the colony, ſeveral arrived from England in January 1793, and fixed themſelves in a ſituation which they called *Liberty Plains*. To one of theſe, Thomas Roſe, a farmer from Dorſetſhire, and his family of a wife and four children, 120 acres were allotted. The conditions under which theſe people agreed to ſettle were, "to have their paſſage provided by government (A); an aſſortment of tools and implements to be given to them out of the ſtores; that they ſhould be ſupplied with two years proviſions; that their lands ſhould be granted free of expence; the ſervice of convicts alſo to be aſſigned to them free of expence; and that thoſe convicts ſhould be ſupplied with two years rations and one year's clothing."

Among the great difficulties with which this infant eſtabliſhment had to ſtruggle, not the leaſt was that of procuring cattle. Of thoſe which were embarked in England and other places for the colony, a very ſmall proportion only arrived; for of 15 bulls and 119 cows, which had been embarked for Botany Bay, only 3 bulls and 28 cows were landed at the ſettlement. It was not until the arrival of the Endeavour, Captain Bampton, in 1795, that the mode of conveying cattle to the colony without material loſs was diſcovered. In that veſſel, out of 130 head which he embarked at Bombay, one cow only died on the paſſage, and that too on the day before his arrival.

The ſcarcity of cattle naturally raiſed their price. Even after this laſt importation, an Engliſh cow in calf ſold for L.80.

Notwithſtanding the various obſtacles which induſtry had met in the cultivation of this ſettlement, it yet made conſiderable advances; for in October 1793, the value of land had ſo riſen, that one ſettler ſold his allotment of 30 acres for as many pounds; and one farm, with the houſe, &c. ſold for L.100. The value of ground, indeed, was conſiderably enhanced by government agreeing to purchaſe the redundance of the produce of the ſettlers at fixed prices. Wheat properly dried and cleanſed was received from the ſettlers at Sydney, by the commiſſary, at 10s. per buſhel. Some cultivators, however, had deviſed another mode of diſpoſing of their corn. One of them, whoſe ſituation was near Parramatta, having obtained a ſmall ſtill from England, found it more advantageous to draw an ardent diabolical ſpirit from his wheat, than to lend it to the ſtores. From one buſhel of wheat he obtained nearly five quarts of ſpirit, which he ſold or paid in exchange for labour, at the rate of five or ſix ſhillings per quart. A better uſe was made of grain by another ſettler; who, having a mill, ground it, and procured 44lb. of good flour, from a buſhel of wheat taken at 59lb. This flour he ſold at 4d. per lb.

By a return of the number of perſons in New South Wales and Norfolk Iſland in April 1794, it appeared that there were in all 4414, including women and children; the annual expence of whom, to the mother-country, Mr Collins eſtimates at L.161,101. Rapid ſtrides, however, were at that time making towards independence, if not towards an ability of repaying to England a part of what the ſettlement had coſt her. Already the colony lived on grain of its own growth, and an increaſe of live ſtock was become almoſt certain. There were now 4665 acres of ground cleared for cultivation; more than half of which had been effected by thoſe who had become ſettlers in the courſe of fifteen months.

To this ſpirit of improvement ſuch a check was given in September 1794, that not more than a third of government ground, and a fifth of ground belonging to individuals, was in cultivation 1795. As this event has been miſrepreſented, we ſuſpect purpoſely, by ſome of our journaliſts, we ſhall give the true account of it in the words of Mr Collins himſelf

"The Francis ſchooner (ſays he) returned from Norfolk, having been abſent about eight weeks and three days. From Mr King, who commanded in that iſland, we learned that his harveſt had been prodigiouſly productive. He had purchaſed from the firſt crops, which the ſettlers had brought to market, upwards of 11,000 buſhels of maize; and bills for the amount were drawn by him in favour of the reſpective ſettlers; but requiring the ſanction of the Lieutenant governor, they were now ſent to Port Jackſon. Mr King had been partly induced to make this proviſional kind of purchaſe, under an idea, that the corn would be acceptable at Port-Jackſon, and alſo in compliance with the conditions on which the ſettlers had received their reſpective allotments under the regulations of Governor Phillip; that is to ſay, that their overplus grain ſhould be purchaſed at a fair market price. Being, however, well ſtocked with that article already, the Lieutenant governor did not think himſelf juſtifiable in putting the crown to ſo great an expence (nearly L.3000 Sterling), and declined accepting the bills." This naturally excited ſome diſcontents in Norfolk Iſland, and one or two ſettlers gave up their farms; but immediately on the arrival of Governor Hunter, he paid for the corn, and tranquillity was reſtored to the iſland.

Though ſeveral quarrels had occurred between the natives and individuals among the coloniſts, yet it was ſuppoſed that our people were in general the aggreſſors. The governor had taken much pains to inſpire the natives with confidence, and had in a great meaſure ſucceeded. To theft they were naturally and irreſiſtibly inclined; but, like other ſavages, they ſeemed unconſcious of the crime, and were ſeldom deterred by detection from mixing with the coloniſts. At a ſettlement which had early been formed at a river called the *Hawkeſbury* (and at which, cultivation having gone on well, there was, in courſe, much grain to ſtimulate to depredation), the natives aſſumed a more formidable appearance.

"At that ſettlement (ſays Mr Collins) an open war ſeemed

Wales.

(A) Government paid for the paſſage of each perſon above ten years of age L.8, 8s. and one ſhilling per day for victualling them.

Wales. seemed about this time to have commenced between the natives and the settlers: and word was received overland, that two people were killed by them; one a settler of the name of Wilson, and the other a freeman, one William Thorp, who had hired himself to this Wilson as a labourer. The natives appeared in large bodies, men, women, and children, provided with blankets and nets to carry off the corn, of which they appeared as fond as the natives who lived among us, and seemed determined to take it whenever and wherever they could meet with opportunities. In their attacks they conducted themselves with much art; but where that failed they had recourse to force; and on the least appearance of resistance made use of their spears or clubs. To check at once, if possible, these dangerous depredators, Captain Paterson directed a party of the corps to be sent from Paramatta, with instructions to destroy as many as they could meet with of the wood tribe (Bè-diagal); and, in the hope of striking terror, to erect gibbets in different places, whereon the bodies of all they might kill were to be hung. It was reported that several of these people were killed in consequence of this order; but none of their bodies being found (perhaps if any were killed they were carried off by their companions), the number could not be ascertained. Some prisoners, however, were taken, and sent to Sydney; one man (apparently a cripple), five women, and some children. One of the women, with a child at her breast, had been shot through the shoulder, and the same shot had wounded the babe. They were immediately placed in a hut near our hospital, and every care taken of them that humanity suggested. The man was said, instead of being a cripple, to have been very active about the farms, and instrumental in some of the murders which had been committed. In a short time he found means to escape, and by swimming reached the north shore in safety; whence, no doubt, he got back to his friends. Captain Paterson hoped, by detaining the prisoners and treating them well, that some good effect might result; but finding, after some time, that coercion, not attention, was more likely to answer his ends, he sent the women back. While they were with us, the wounded child died, and one of the women was delivered of a boy, which died immediately. On our withdrawing the party, the natives attacked a farm nearly opposite Richmond Hill, belonging to one William Rowe, and put him and a very fine child to death; the wife, after receiving several wounds, crawled down the bank, and concealed herself among some reeds half immersed in the river, where she remained a considerable time without assistance: being at length found, this poor creature, after having seen her husband and her child slaughtered before her eyes, was brought into the hospital at Paramatta, where she recovered, though slowly, of her wounds."

By the vigorous measures which were adopted, the colony, towards the close of 1796, had acquired a degree of strength which seemed to ensure its future prosperity. Not only the necessary edifices were raised for the habitations of its people, but some for the purposes of religion, amusement, &c. A playhouse had been erected at the expence of some persons who performed in it for their own emolument, and who admitted auditors at one shilling each. A convenient church had been built, a printing-press had been set up, the civil court was open for the recovery of debts by action and for proving wills, licences had been issued to regulate the sale of spirits, and passage-boats were established for the convenience of communication between the different settlements. In the houses of individuals were to be found most of the comforts, and not a few of the luxuries, of life; and, in a word, the former years of famine, toil, and difficulty, were now exchanged for those of plenty, ease, and pleasure.

The quantity of ground at this time in cultivation was 5410 acres; of which 2547 were occupied by settlers. The number of persons in New South Wales and its dependencies amounted to 4848. The price of labour, however, compared with the prices of provisions (as given in Mr Collins's Tables), does not appear so high as to enable the workman to live very comfortably. He who receives but three shillings for his day's work, and gives two shillings for a pound of mutton, fifteen pence for a pound of pork, and half of that sum for a pound of flour, will scarcely derive from his mere labour the support necessary for a family.

That many things are yet wanted to give full effect to the advantages which the colony now enjoys, M Collins declares in the following paragraph, with which he concludes his account:

"The want at this time of several public buildings in the settlement has already been mentioned. To this want must be added, as absolutely necessary to the well-being and comfort of the settlers, and the prosperity of the colony in general, that of a public store, to be opened on a plan, though not exactly the same, yet as liberal as that of the Island of St Helena, where the East India Company issue to their own servants European and Indian goods at 10 *per cent.* advance on the prime cost. Considering our immense distance from England, a greater advance would be necessary; and the settlers and others would be well satisfied, and think it equally liberal, to pay 50 *per cent.* on the prime cost of all goods brought from England; for at present they pay never less than 100, and frequently 1000, *per cent.* on what they have occasion to purchase. It may be supposed that government would not choose to open an account, and be concerned in the retail of goods; but any individual would find it to his interest to do this, particularly if assisted by government in the freight; and the inhabitants would gladly prefer the manufactures of their own country to the sweepings of the Indian bazars.

"The great want of men in the colony must be supplied as soon as a peace shall take place; but the want of respectable settlers may, perhaps, be longer felt; by these are meant men of property, with whom the gentlemen of the colony could associate, and who should be thoroughly experienced in the business of agriculture. Should such men ever arrive, the administration of justice might assume a less military appearance, and the trial by jury, ever dear and most congenial to Englishmen, be seen in New South Wales."

There is, however, one serious difficulty which the colony has not yet overcome, and which, until it be overcome, will certainly prevent such men from settling in New South Wales. Till some staple commodity can be raised for exportation, industrious free settlers will never be tempted to emigrate from Europe to a country where their industry cannot procure the comforts as well

well as the necessaries of life. The American colonies, in their infancy, did not labour under this disadvantage. Tobacco soon became, and still continues to be, an article of such importance, that its cultivation afforded the trans-atlantic farmer a ready exchange for European commodities; whilst in New South Wales there seems to be no vegetable production of much value, except New Zealand hemp, which is produced indeed in great abundance in Norfolk Island, and which Captain Cook long ago pointed out as an article of great importance to the British navy. This is indeed a valuable plant, and grows in all the cliffs of the island, where nothing else will grow, in sufficient abundance to give constant employment to 500 people; yet when Mr Collins left the settlement, there was no more than one loom on the island, and the flay or reed was designed for coarse canvas; nor did they possess a single tool required by flax-dressers or weavers beyond the poor substitutes which they were obliged to fabricate for themselves. In this defect of necessaries for the manufacture, only 18 people could be employed in it; and of these the united labour in a week produced 16 yards of canvas, of the size called N° 7.

Besides a useful manufactory of this plant, which certainly might be established, the colony appears to possess several important advantages. From Mr Collins's narrative, it appears probable that a seal and perhaps a whale fishery might be established with a fair prospect of success; good rich earth is found near Sydney Cove; there are immense strata of coal in the southern part of New Holland; Norfolk Island abounds with lime; and vast quantities of shells, which answer the same purpose, have been found on the main-land. Though the wood in general be not of a durable kind, it appears that there is some good timber near the Hawkesbury river; and at Norfolk Island and New Zealand it is remarkably fine.

* WALPOLE (Horace, Earl of Orford), was the youngest son of the celebrated Sir Robert Walpole, afterwards Earl of Orford, by his first wife, Catharine, daughter of Robert Shorter, Esq; of Bybrook in Kent. He was born 1716; and was educated, first at Eton school, and afterwards at Cambridge. At Eton he formed an intimate acquaintance with the celebrated poet Gray; and they went together on the tour of Europe, in the years 1739, 1740, and 1741. Unhappily they had a dispute in the course of their travels, which produced a separation.

Mr Walpole was able to make a splendid figure during the remainder of his destined course; but poor Gray, after the separation, was obliged to observe a very severe economy. "This difference arose from the difference of their tempers: the latter being, from his earliest years, curious, pensive, and philosophical; the former, gay, lively, and inconsiderate. This, therefore, occasioned their separation at Reggio. Mr Gray went before him to Venice; and staying there till he could find means of returning to England, he made the best of his way home, repassing the Alps, and following almost the same rout, through France, which he had before gone to Italy. In justice to the memory of so respectable a friend, Mr Walpole (says Mr Mason, Life of Gray, 4to, p. 41.) enjoins me to charge him with the chief blame in their quarrel, confessing that more attention, complaisance, and deference, to a warm friendship, and superior judgment and prudence, might have prevented a rupture that gave much uneasiness to them both, and a lasting concern to the survivor; though in the year 1744 a reconciliation was effected between them, by a lady who wished well to both parties."—This event took place after their return to England; but the *wound* in their friendship left a *scar* that never was totally effaced.

We do not, indeed, think that Horace Walpole and Mr Gray were formed, either by nature or by habits, to continue long in a state of intimate friendship. Gray appears to have been a man of the purest moral principles, a friend to religion, pensive, and at least sufficiently conscious of his intellectual powers and intellectual attainments. Walpole's morality was certainly of a looser kind; he seems to have had no religion; he was often unseasonably gay; and to an equal share of intellectual pride, though without equal reason, he added the pride of birth. It can therefore excite no surprise that a man of Gray's independent spirit could not bear the supercilious freaks of such a character.

Mr Walpole was nominated to represent the city of Norwich, when his father visited it July 3d, 1733, having acquired consequence, not only as the son of the minister, but as having attended the Prince of Orange to England in that year. He was chosen member for Collington, in Cornwall, in the parliament which met June 25th, 1741; was a second time in parliament as representative for Castle Rising, in Norfolk, in 1747; and for King's Lynn in 1754 and 1761; and, at the expiration of that parliament, he finally retired from the stage of politics, and confined himself wholly to literary pursuits. He held to his death the office of usher of his Majesty's exchequer, comptroller of the pipe, and clerk of the estreats. Upon the death of his nephew, George, third Earl of Orford, 1791, he succeeded to the title and estates; but that event made so little alteration in his mode of living, that we know not whether he ever took his seat in the house of peers. During almost the whole course of his life he was the victim of the gout, which at last reduced him to a cripple: but it never impaired his faculties; and, to the very moment of death, his understanding seemed to bid defiance to the shock of Nature. He died at his house in Berkesley Square, in 1796, having just entered his 80th year; and was interred in the family vault at Houghton, in a private manner, agreeably to his particular directions.

Horace, Lord Orford, was never married, and, by one of his biographers, his chief mistress through life is said to have been the muse. It is certain that he devoted the greater part of his life to belles lettres and virtú, though he ridiculously affected, in his letters to his friends, to despise learning and learned men, for which he was very properly reprimanded both by Gray and Hume. It was an affectation peculiarly absurd in him, who was constantly publishing something, and who wrote with uncommon acrimony against all who presumed to call in question the fidelity of the picture which he had drawn of Richard III. or indeed to controvert any of his opinions. Hence his antipathy to Johnson, because he was a tory, a Christian, and a rigid moralist; whilst he himself was a whig, an infidel, and such a moralist as could retail, without blushing, all the scandalous anecdotes, whether true or false, of that august family, from

whom he acknowledged his whole fortune to be derived. He had, indeed, another reason for disliking Johnson. Lord Orford shone in conversation, and surpassed all his contemporaries in that kind of talk, which, without dazzling by its wit, always delighted; while Johnson, when roused, knocked down, as by a flash of lightning, his Lordship, and every one else who had the confidence before him to talk profanely. Johnson's wit was original: Lord Orford's consisted of ludicrous stories and of literary and political anecdotes. His works, of which by far the most valuable part has long been in the hands of the public, were collected in 1798, and published in five volumes, 4to. They resemble his conversation, being rather amusing than profound or instructive.

WARING (Edward, M.D.), Lucasian Professor of Mathematics in the university of Cambridge, was the son of a wealthy farmer, of the Old Heath, near Shrewsbury. The early part of his education he received at the free school in Shrewsbury; whence he removed to Cambridge, and was admitted on the 24th of March 1753 a member of Magdalen college. Here his talents for abstruse calculation soon developed themselves, and, at the time of taking his degree, he was considered as a prodigy in those sciences which make the subject of the bachelor's examination. The name of Senior Wrangler, or the first of the year, was thought scarcely a sufficient honour to distinguish one who so far outshone his contemporaries; and the merits of John Jebb were sufficiently acknowledged, by being the second in the list. Waring took his first, or bachelor's degree, in 1757, and the Lucasian Professorship became vacant before he was of sufficient standing for the next, or master's degree, which is a necessary qualification for that office. This defect was supplied by a royal mandate, through which he became master of arts in 1760; and shortly after his admission to this degree, the Lucasian Professor.

The royal mandate is too frequently a screen for indolence; and it is now become almost a custom, that heads of colleges, who ought to set the example in discipline to others, are the chief violaters of it, by making their office a pretext for taking their doctor's degree in divinity, without performing those exercises which were designed as proofs of their qualifications. Such indolence cannot be imputed to Waring; yet several circumstances, previous to his election into the professorial chair, discovered that there was, at least, one person in the university who disapproved of the anticipation of degrees by external influence.—Waring, before his election, gave a small specimen of his abilities, as proof of his qualification for the office which he was then soliciting; and a controversy on his merits ensued: Dr Powell, the master of St John's college, attacking, in two pamphlets, the Professor; and his friend, afterwards Judge Wilson, defending. The attack was scarcely warranted by the errors in the specimen; and the abundant proofs of talents in the exercise of the professorial office are the best answers to the sarcasms which the learned divine amused himself in casting on rising merit. An office held by a Barrow, a Newton, a Whiston, a Cotes, and a Sanderson, must excite an ingenuous mind to the greatest exertions; and the new Professor, whatever may have been his success, did not fall behind any of his predecessors, in either zeal for the science, or application of the powers of his mind, to extend its boundaries. In 1762, he published his Miscellanea Analytica; one of the most abstruse books written on the abstrusest parts of algebra. This work extended his fame over all Europe. He was elected, without solicitation on his part, member of the societies of Bononia and Gottingen; and received flattering marks of esteem from the most eminent mathematicians at home and abroad. The difficulty of this work may be presumed from the writer's own words, "I cannot say that I know any one who thought it worth while to read through the whole, and perhaps not the half of it."

Waring.

Mathematics did not, however, engross the whole of his attention. He could dedicate some time to the study of his future profession; and in 1767, he was admitted to the degree of doctor of physic; but, whether from the incapacity of uniting together the employments of active life with abstruse speculation, or from the natural diffidence of his temper, for which he was most peculiarly remarkable; the degree which gave him the right of exercising his talents in medicine was to him merely a barren title. Indeed he was so embarrassed in his manners before strangers, that he could not have made his way in a profession in which so much is done by address; and it was fortunate that the case of his circumstances permitted him to devote the whole of his time to his favourite pursuit. His life passed on, marked out by discoveries, chiefly in abstract science; and by the publication of them in the Philosophical Transactions, or in separate volumes, under his own inspection. He lived some years after taking his doctor's degree, at St Ives, in Huntingdonshire. While at Cambridge he married—quitted Cambridge with a view of living at Shrewsbury; but the air or smoke of the town being injurious to Mrs Waring's health, he removed to his own estate at Plaisley, about 8 miles from Shrewsbury, where he died in 1797, universally esteemed for inflexible integrity, modesty, plainness, and simplicity of manners. They who knew the greatness of his mind from his writings looked up to him with reverence everywhere; but he enjoyed himself in domestic circles with those chiefly among whom his pursuits could not be the object either of admiration or envy. The outward pomp which is affected frequently in the higher departments in academic life, was no gratification to one whose habits were of a very opposite nature; and he was too much occupied in science to attend to the intrigues of the university. There, in all questions of science, his word was the law; and at the annual examination of the candidates for the prize instituted by Dr Smith, he appeared to the greatest advantage. The candidates were generally three or four of the best proficients in the mathematics at the previous annual examination for the bachelor's degree, who were employed from nine o'clock in the morning to ten at night, with the exception of two hours for dinner, and twenty minutes for tea, in answering, *viva voce*, or writing down answers to the professor's questions, from the first rudiments of philosophy to the deepest parts of his own and Sir Isaac Newton's works. Perhaps no part of Europe affords an instance of so severe a process; and there was never any ground for suspecting the Professor of partiality.

lity. The zeal and judgment with which he performed this part of his office cannot be obliterated from the memory of those who passed through his fiery ordeal

Wishing to do ample justice to the talents and virtue of the Professor, we feel ourselves somewhat at a loss in speaking of the writings by which alone he will be known to posterity. He is the discoverer, according to his own account, of nearly 400 propositions in the analytics. This may appear a vain glorious boast, especially as the greater part of those discoveries are likely to sink into oblivion; but he was, in a manner, compelled to make it by the insolence of Lalande, who, in his life of Condorcet, asserts that, in 1764, there was no first-rate analyst in England In reply to this assertion, the Professor, in a letter to Dr Maskelyne, first mentions, with proper respect, the inventions and writings of Harriot, Briggs, Napier, Wallis, Halley, Bruncker, Wren, Pell, Barrow, Mercator Newton, De Moivre, Maclaurin, Cotes, Stirling, Taylor, Simpson, Emerson, Landen, and others; of whom Emerson and Landen were living in 1764. He then gives a fair and full detail of his own inventions, of which many were published anterior to 1764; and concludes his letter in these words.

"I know that Mr Lalande is a first-rate astronomer, and writer of astronomy; but I never heard that he was much conversant in the deeper parts of mathematics; for which reason I take the liberty to ask him the following questions:

"Has he ever read or understood the writings of the English mathematicians: and, as the question comes from me, I subjoin, particularly of mine? If the answer be in the negative, as it is my opinion, if his answer be the truth, that it will, then there is an end of all further controversy;—but if he asserts that he has, which is more than Condorcet did by his own acknowledgment, then he may know, from the enumeration of inventions made in the prefaces, with some subsequent ones added, that they are said to amount to more than 400 of one kind or other. Let him try to reduce those to as low a number as he can, with the least appearance of candour and truth; and then let him compare the number with the number of inventions of any French mathematician or mathematicians, either in the present or past times, and there will result a comparison (if I mistake not) not much to his liking; and, further, let him compare some of the first inventions of the French mathematicians with some of the first contained in my works, both as to utility, generality, novelty, difficulty, and elegance, but wisely as to utility, there is little contained in the deep parts of any science; he will find their difficulty and novelty from his difficulty of understanding them, and his never having read any thing similar before; their generality, by the application of them; principles of elegance will differ in different persons.—I must say, that he will probably not find the difference expected. After or before this inquiry is instituted for mine, let him perform the same for the other English mathematicians; and when he has completed such inquiries, and not before, he will become a judge of the justice of his assertion; but I am afraid that he is not a sufficient adept in these studies to institute such inquiries; and if he was, such inquiries are invidious, troublesome, and of small utility."

By mathematical readers this account, which was not published by the Professor himself, is allowed to be very little, if at all, exaggerated. Yet if, according to his own confession, "few thought it worth their while to read even half of his works," there must be some grounds for this neglect, either from the difficulty of the subject, the unimportance of the discoveries, or a defect in the communication of them to the public. The subjects are certainly of a difficult nature, the calculations are abstruse; yet Europe contained many persons not to be deterred by the most intricate theorems. Shall we say then, that the discoveries were unimportant? If this were really the case, the want of utility would be a very small disparagement among those who cultivate science with a view chiefly to entertainment and the exercise of their rational powers. We are compelled, then, to attribute much of this neglect to a perplexity in style, manner, and language; the reader is stopped at every instant, first to make out the writer's meaning, then to fill up the chasm in the demonstration. He must invent anew every invention; for, after the enunciation of the theorem or problem, and the mention of a few steps, little assistance is derived from the Professor's powers of explanation. Indeed, an anonymous writer, certainly of very considerable abilities, has aptly compared the works of Waring to the heavy appendages of a Gothic building, which add little of either beauty or stability to the structure.

A great part of the discoveries relate to an assumption in algebra, that equations may be generated by multiplying together others of inferior dimensions. The roots of these latter equations are frequently terms called *negative* or *impossible*; and the relation of these terms to the coefficients of the principal equation is a great object of inquiry. In this art the professor was very successful, though little assistance is to be derived from his writings in looking for the real roots. We shall not, perhaps, be deemed to depreciate his merits, if we place the series for the sum of the powers of the roots of any equation among the most ingenious of his discoveries; yet we cannot add, that it has very usefully enlarged the bounds of science, or that the algebraist will ever find occasion to introduce it into practice. We may say the same on many ingenious transformations of equations, on the discovery of impossible roots, and similar exertions of undoubtedly great talents. They have carried the assumption to its utmost limits; and the difficulty attending the speculation has rendered persons more anxious to ascertain its real utility; yet they who reject it may occasionally receive useful hints from the Miscellanea Analytica.

The first time of Waring's appearing in public as an author was, we believe, in the latter end of the year 1759, when he published the first chapter of the Miscellanea Analytica, as a specimen of his qualifications for the professorship; and this chapter he defended, in a reply to a pamphlet, intitled, "Observations on the First Chapter of a book called Miscellanea Analytica." Here the Professor was strangely puzzled with the common paradox, that nothing divided by nothing may be equal to various finite quantities, and has recourse to unquestionable authorities in proof of this position. The names of Maclaurin, Sanderson, De Moivre, Bernoulli, Monmort, are ranged in favour of his opinion: But Dr Powell was not so easily convinced, and returns to the charge in defence of the Observations; to which the

Waring. Professor replied in a letter to the Rev. Dr Powell, Fellow of St John's college, Cambridge, in answer to his Observations, &c. In this controversy, it is certain that the Professor gave evident proofs of his abilities; though it is equally certain that he followed too implicitly the decisions of his predecessors. No apparent advantage, no authority whatever, should induce mathematicians to swerve from the principles of right reasoning, on which their science is supposed to be peculiarly founded. According to Maclaurin, Dr Waring, and others, If $P = \frac{a-x}{a^2-x^2}$, then, when $x = a$, P is equal to $\frac{1}{2a}$; for, say they, $\frac{a-x}{a^2-x^2}$ is equal to $\frac{a-x}{a-x} \times \frac{1}{a+x}$; that is, when x is equal to a, $P = \frac{1}{a+x}$, or $\frac{1}{2a}$. But when x is equal to a, the numerator and denominator of the fraction $\frac{a-x}{a^2-x^2}$ are both, in their language, equal to nothing. Therefore, nothing divided by nothing is equal to $\frac{1}{2a}$. In the same manner, $\frac{a-x}{a^3-x^3} = \frac{1}{a^2+ax+x^2} \times \frac{a-x}{a-x}$, which, when x is equal to a, becomes $\frac{1}{3a^2}$. Therefore, nothing divided by nothing is equal to $\frac{1}{3a^2}$, or $\frac{1}{3a^2} = \frac{1}{2a}$; that is, $\frac{1}{3a} = \frac{1}{2}$; which is absurd. But we need only trace back our steps to see the fallacy in this mode of reasoning. For P is equal to some number multiplied into $\frac{a-x}{a-x}$; that is, when x is equal to a, P is equal to some number multiplied into nothing, and divided by nothing; that is, P is, in that case, no number at all. For $a-a$ cannot be divided by $a-x$ when x is equal to a, since, in that case, $a-x$ is no number at all.

If, in the beginning of his career, the Professor could admit such paralogisms into his speculations, and the writings of the mathematicians, for nearly a century before him, may plead in his excuse, we are not to be surprised that his discoveries should be built rather on the assumptions of others than on any new principles of his own. Acquiescing in the strange notion, that nothing could be divided by nothing, and produce a variety of numbers, he as easily adopted the position, that an equation has as many roots as it has dimensions.—Thus 2 and — 4 are said to be roots of the equation $x^2 + 2x = 8$, though 4 can be the root only of the equation; $x^2 - 2x = 8$, which differs so materially from the preceding, that in one case $2x$ is added, in the other case it is subtracted from x^2.

Allowances being made for this error in the principles, the deductions are, in general, legitimately made; and any one, who can give himself the trouble of demonstrating the propositions, may find sufficient employment in the Professor's analytics. Perhaps it will be sufficient for a student to devote his time to the simplest case $x^n \pm 1 = 0$; and when he has found a few thousand roots of + 1 and — 1, the publication of them may afford to posterity a strong proof of the ingenuity of their predecessors, and the application of Waring. the powers of their mind to useful and important truths. In this exercise may be consulted the method given by the Professor, of finding a quantity, which, multiplied into a given irrational quantity, will produce a rational product, or consequently exterminate irrational quantities out of a given equation; but if an irrational quantity cannot come into an equation, the utility of this invention will not be admitted without hesitation.

The "Proprietates Algebraicarum Curvarum," published in 1772, necessarily labour under the same defects with the Miscellanea Analytica, the Meditationes Algebraicæ, published in 1770, and the Meditationes Analyticæ, which were in the press during the years 1773, 1774, 1775, 1776. These were the chief and the most laborious works edited by the Professor; and in the Philosophical Transactions is to be found a variety of papers, which alone would be sufficient to place him in the first rank in the mathematical world. The nature of them may be seen from the following catalogue.

Vol LIII. p. 294, Mathematical Problems.—LIV. 193. New Properties in Conics.—LV. 143. Two Theorems in Mathematics.—LXIX Problems concerning Interpolations.—86. A General Resolution of Algebraical Equations —LXXVI. 81. On Infinite Series. LXXVII. 71. On Finding the Values of Algebraical Quantities by Converging Serieses, and Demonstrating and Extending Propositions given by Pappus and others.—LXXVIII. 67. On Centripetal Forces.—*Ib.* 588. On some Properties of the Sum of the Division of Numbers.—LXXIX. 166 On the Method of Correspondent Values, &c.—*Ib.* 185. On the Resolution of Attractive Powers.—LXXXI. 146. On Infinite Serieses.—LXXXIV. 385—415. On the Summation of those Serieses whose general term is a determinate function of z, the distance of the term of the Series.

For these papers, the Professor was, in 1784, deservedly honoured by the Royal Society with Sir Godfrey Copley's medal; and most of them afford very strong proofs of the powers of his mind, both in abstract science, and the application of it to philosophy; though they labour, in common with his other works, under the disadvantage of being clothed in a very unattractive form. The mathematician, who has resolution to go through them, will not only add much to his own knowledge, but be usefully employed in dilating on those articles for the benefit of the more general reader. We might add in this place, a work written on morals and metaphysics in the English language; but as a few copies only were presented to his friends, and it was the Professor's wish that they should not have a more extensive circulation, we shall not here enlarge upon its contents.

In the mathematical world, the life of Waring may be considered as a distinguished æra. The strictness of demonstration required by the ancients had gradually fallen into disuse, and a more commodious, though almost mechanical mode by algebra and fluxions took its place, and was carried to the utmost limit by the Professor. Hence many new demonstrations may be attributed to him, but 400 discoveries can scarcely fall to the lot of a human being. If we examine thoroughly those which our Professor would distinguish by such names, we shall find many to be mere deductions, o-

thers, as in the solution of biquadratics, anticipated by former writers But if we cannot allow to him the merit of so inventive a genius, we must applaud his assiduity; and, distinguished as he was in the scientific world, the purity of his life, the simplicity of his manners, and the zeal which he always manifested for the truths of the Gospel, will intitle him to the respect of all who do not esteem the good qualities of the heart inferior to those of the head.

WARTON (Joseph, D. D.) was born either towards the end of the year 1721, or in the beginning of the year 1722. He was the eldest son of Thomas Warton, B. D. who had been fellow of Magdalen College, Oxford; poetry professor from the year 1718 to 1728, and vicar of Basingstoke in Hampshire, and of Cobham in Surrey. Where the subject of this memoir was born we have not learned, though, were we to hazard a conjecture, we would say that it was in Oxford, as his father probably resided in that city during his professorship.

Our knowledge of the private history of Dr Warton is indeed extremely limited. We do not even know at what school, or in what college, he was educated; tho' it was probably at Winchester school, and certainly in some of the colleges in the university of Oxford For many years, he was successively under and upper master of Winchester college; but resigned the last of these offices when he found the infirmities of age coming upon him; and was succeeded by Dr Goddard the present excellent master. He was likewise prebendary of the cathedral church of Winchester, and rector of Wickham in Hampshire, where he died, aged 78.

His publications are few, but valuable. A small collection of poems, without a name, was the first of them, and contained the Ode to Fancy, which has been so much and so deservedly admired. They were all of them afterwards printed in Dodsley's collection. He was also a considerable contributor to the Adventurer, published by Dr Hawkesworth; and all the papers which contain criticisms on Shakespeare were written by him and his brother Thomas Warton, the subject of the next article.

The first volume of his Essay on the Life and Writings of Pope was published, had passed through several editions, and an interval of between 20 and 30 years had elapsed, before he gave a second volume of that elegant and instructive work to the world. He had not only meditated, but had collected materials for a literary history of the age of Leo X.; and proposals were actually in circulation for a work of that kind; but it is probable that the duties of his station did not leave him the necessary leisure for an undertaking which required years of seclusion and independence. His last and late work, which he undertook for the booksellers at a very advanced age, was an edition of Pope's Works, that has not altogether satisfied the public expectation. He retained, with great propriety indeed, many of the notes of Warburton; but is severely reprehended by the author of the Pursuits of Literature for suppressing the name of that prelate on his title-page, or including it only, as subordinate to his own, in the general expression *others*.

Dr Warton was cheerful in his temper, convivial in his disposition, of an elegant taste and lively imagination, with a large portion of scholarship, and a very general knowledge of the Belles Lettres of Europe; it may be presumed that Dr Warton possessed, beyond most men, the power of enlivening Classical Society. He was the intimate friend of Dr Johnson; was seen at the parties of Mrs Montague, as well as at the table of Sir Joshua Reynolds, and was an original member of the Literary Club. He possessed a liberal mind, a generous disposition, and a benevolent heart. He was not only admired for his talents and his knowledge, but was beloved for those qualities which are the best gifts of this imperfect state.

WARTON (Thomas), the brother of the preceding, was born in the year 1728. He received, as we have reason to believe, the first part of his education at Winchester; and at the age of 16 was entered a commoner of Trinity College, Oxford, under the tuition of Mr Geering. *Biog. Dict.*

He began his poetical career at an early age. In 1745, he published five pastoral eclogues, in which are beautifully described the miseries of war to which the shepherds of Germany were exposed. Not long after, in the year 1748, he had full scope afforded for the exertion of his genius. It is well known that Jacobite principles were suspected to prevail in the university of Oxford about the time of the rebellion in the year 1745. Soon after its suppression, the drunkenness and folly of some young men gave offence to the court, in consequence of which a prosecution was instituted in the court of King's Bench, and a stigma was fixed on the vice-chancellor and some other heads of colleges in Oxford. Whilst this affair was the general subject of conversation, Mr Malon published his "Isis," an elegy, in which he adverts to the above-mentioned circumstances. In answer to this poem, Mr Warton, encouraged by Dr Huddesford, the president of his college, published in 1749, "The Triumph of Isis," which excelled more in manly expostulation and dignity than the poem that produced it did in neatness and elegance. With great poetical warmth, and a judicious selection of circumstances, he characterises the eminent men who had been educated in Oxford, and draws a striking and animated portrait of Dr King, the celebrated public orator of that time. The whole poem shews the early maturity of his genius, and is finished with happy diligence.

In the year 1751, he succeeded to a fellowship of his college, and was thus placed in a situation easy and independent, and particularly congenial with his habits of retirement and study. In 1753, appeared his observations on "The Faery Queen of Spencer," in 8vo, a work which he corrected, enlarged, and republished, in two volumes crown octavo, in the year 1762. He sent a copy of the first edition to Dr Johnson, who, in a letter to him upon the subject, expressed this handsome compliment: "I now pay you a very honest acknowledgement for the advancement of the literature of our native country: you have shewn to all, who shall hereafter attempt the study of ancient authors, the way to success, by directing them to the perusal of the books which these authors had read."

In 1754, Dr Johnson visited Oxford for the first time after he had quitted residence there. Much of his time was spent with Mr Warton; and there appeared to have been a considerable degree of confidential intercourse between them upon literary subjects, and particularly on their own works. A pleasing account of

Warton.

this visit was communicated by Mr Warton to Mr Boswell, who has inserted it in his life of Johnson.

In 1755, Mr Warton exerted himself to procure for his friend the degree of master of arts by diploma from the university of Oxford; an honour which Johnson esteemed of great importance to grace the title page of his dictionary which he was about to publish. In 1756, Mr Warton was elected professor of poetry, which office he held for the usual term of ten years. His lectures were remarkable for elegance of diction and justness of observation. One of them, on the subject of pastoral poetry, was afterwards prefixed to his edition of Theocritus. In 1758, he contributed to assist Dr Johnson in the subscription to his edition of Shakespeare, and furnished him with some valuable notes. The Doctor remarks, in a letter to him, when soliciting his farther aid, "It will be reputable to my work, and suitable to your professorship, to have something of yours in my notes"

From the Clarendon press, in the year 1766, he published "Anthologiæ Græcæ, a Constantino Cephalâ conditæ, Libri tres," in 2 vols, 12mo. He concludes the learned and classical preface to this work, which is replete with accurate remarks on the Greek epigram, in the following words, which mark this publication for his own: "Vereor ut hactenus in plexendis florum corollis otium nimis longum pertraxerim. Proximè sequetur, cui nunc omnes operas et vires intendo, Theocritus. Interea quasi promulsidem convivii Lectoribus meis elegantias hasce vetustatis eruditæ propino."

In the year 1770, he conferred a similar honour up on the academical press by his edition of Theocritus, in 2 vols, 8vo. He undertook this work by the advice of Judge Blackstone, then fellow of All-Souls College, and an ardent promoter of every publication that was likely to do credit to the Clarendon press. This elaborate publication reflects no small credit on the learning, diligence, and taste of the editor.

In 1771, he was elected a fellow of the Antiquarian Society, and was presented by the Earl of Lichfield to the small living of Kiddington in Oxfordshire, which he held till his death. He likewise in this year published an improved account of "The Life of Sir Thomas Pope, founder of Trinity College, Oxford. In composing these memoirs, he bestowed much labour and research, and shewed great judgment in the arrangement of his materials. But possibly, in his ardour to pay a debt of gratitude, he has not sufficiently considered what was due to his own fame. The same strength of description and vigour of remark would have better suited the life of some eminently distinguished character, and extended the reputation of the author as a biographer beyond the circle of those academical readers who are influenced by the same feelings of veneration, respect, and gratitude which prompted Mr Warton to compose this work. The preface contains some excellent remarks on biographical writing.

The plan for a history of English poetry was laid by Pope, enlarged by Gray: but to bring an original plan nearly to a completion was reserved for the perseverance of Warton. In 1774 appeared his first volume; in 1778, the second and third; which brings the narrative down to the commencement of the reign of Elizabeth in 1581. This work displays the most singular combination of extraordinary talents and attainments. It unites the deep and minute researches of the antiquary with the elegance of the classical scholar and the skill of the practised writer. The style is vigorous and manly; the observations acute and just; and the views of the subject are extensive and accurate.

In 1777, he collected his poems into an octavo volume, containing miscellaneous pieces, odes, and sonnets. This publication may be considered in some measure original; there being only seven pieces that had before appeared, and near three times that number which were then printed for the first time.

In vindication of the opinion he had given in his second volume of "The History of Poetry," relative to the ingenious attempt of Chatterton to impose upon the public, he produced, in 1782, "An Inquiry into the Authenticity of the Poems attributed to Rowley." In this excellent pamphlet the principles of true criticism are laid down, an appeal is properly made to the internal evidence of the poems; and upon these grounds it is proved, in the most satisfactory manner, that they could not have been written by a monk of the fourteenth century.

The year 1785 brought him those distinctions which were no less honourable to those who conferred than to him who received them. He was appointed poet laureat on the death of Whitehead, and elected Camden professor of ancient history on the resignation of Dr Scott. His inauguration lecture was delivered in a clear and impressive manner from the professorial chair. It contained excellent observations on the Latin historians, and was written in a strong, perspicuous, and classical style. In his odes, the vigour and brilliancy of his fancy were not prostituted to an insipid train of courtly compliments: each presents an elegant specimen of descriptive poetry, and as all of them have only a slight relation to the particular occasion on which they were written, and have always a view to some particular and interesting subject, they will be perused with pleasure as long as this species of composition is admired.

He made occasional journeys to London to attend the literary club, of which he was some years a member; and to visit his friends, particularly Sir Joshua Reynolds. At his house he was sure to meet persons remarkable for fashion, elegance, and taste.

His last publication, except his official odes, consisted of Milton's smaller poems. A quarto edition appeared in 1790, with corrections and additions. The great object of these notes is to explain the allusions of Milton, to trace his imitations, and to illustrate his beauties.

Until he reached his sixty second year, he continued to enjoy vigorous and uninterrupted health. On being seized with the gout, he went to Bath, and flattered himself, on his return to college, that he was in a fair way of recovery. But the change that had taken place in his constitution was visible to his friends On Thursday, May 20, 1790, he passed the evening in the common room, and was for some time more cheerful than usual. Between ten and eleven o'clock he was struck with the palsy, and continued insensible till his death, which happened the next day at two o'clock. On the 27th, his remains were interred in the college chapel with the most distinguished academical honours.

Warton. The inscription upon the flat stone which is placed over his grave contains only an enumeration of his preferments.

Such was the general conduct and behaviour of Mr Warton as to render him truly amiable and respectable. By his friends he was beloved for his open and easy manners; and by the members of the university at large he was respected for his constant residence, strong attachment to Alma Mater, his studious pursuits, and high literary character In all parties where the company accorded with his inclination, his conversation was easy and gay, enlivened with humour, enriched with anecdote, and pointed with wit. Among his peculiarities it may be mentioned that he was fond of all military sights. He was averse to strangers, particularly to those of a literary turn; and yet he took a great pleasure in encouraging the efforts of rising genius, and assisting the studious with his advice; as many of the young men of his college, who shared his affability and honoured his talents, could testify. He was bred in the school of punsters; and made as many good ones as Barton and Leigh, the celebrated word-hunters of his day. Under the mask of indolence, no man was more busy; his mind was ever on the wing in search of some literary prey. Although, at the accustomed hours of Oxford study, he was often seen sauntering about, and conversing with any friend he chanced to meet; yet, when others were wasting their mornings in sleep, he was indulging his meditations in his favourite walks, and courting the Muses. His situation in Oxford was perfectly congenial with his disposition, whether he indulged his sallies of pleasantry in the common room, retired to his own study, or to the Bodleian library; sauntered on the banks of his favourite Cherwell, or surveyed, with the enthusiastic eye of taste, the ancient gateway of Magdalen College, and other specimens of Gothic architecture.

The following is a list of Mr Warton's works: 1. "Five Pastoral Eclogues," 4to, 1745. Reprinted in Pearch's Collection of Poems. 2. "The Pleasures of Melancholy," written in 1745; first printed in Dodsley's Collection, and afterwards in the Collection of Mr Warton's Poems 3. "Progress of Discontent," written in 1746. First printed in the "Student," a periodical paper. 4. "The Triumph of Isis, a Poem," 4to, 1750. 5. "Newmarket, a Satire," folio, 1751. 6. "Ode for Music," performed at the theatre in Oxford 1751. 7. "Observations on the Faerie Queen of Spenser," 8vo, 1754. 8. "Inscriptionum Metricarum Delectus," 4to, 1758. 9 "A Description of the City, College, and Cathedral, of Winchester," 8vo, no date. 10. "The Life of Sir Thomas Pope," in the 5th volume of the Biographia Britannica," republished in 1772. 11. "The Life and literary Remains of Ralph Bathurst, M. D. Dean of Wells, and President of Trinity College in Oxford," 1761. 12. "A Companion to the Guide, and a Guide to the Companion," 12mo, 1762. 13. "The Oxford Sausage," in which several Poems by Warton. 14. "Anthologiæ Græcæ a Constantino Cephalâ conditæ Libri tres," 2 tom. 1766. 15. "Theocritis Syracusii quæ supersunt, cum Scholiis Græcis," &c 2 tom. 4to, 1770. 16. "History of English Poetry, from the Close of the 11th to the Commencement of the 18th Century," 4to, Vol. I. 1774. Vol. II. 1778. Vol. III. 1781 17. "Poems," 8vo, 1777 18. "Specimen of a History of Oxfordshire," 1783. 19. "An Enquiry into the Authenticity of the Poems attributed to Thomas Rowley," 8vo, 1782. 20. Verses on Sir J. Reynolds's painted Window in New College Chapel. 4to." 1782. 21. "Poems on several Occasions, by John Milton, with Notes critical and explanatory," 8vo, 1785.

Washington.

WASHINGTON (George), whose name is likely to live as long as that of any modern, was born on the 11th of February 1732, in the parish of Washington, Virginia. He was descended from an ancient family in Cheshire, of which a branch had been established in Virginia about the middle of the 17th century. We are not acquainted with any remarkable circumstances of his education or his early youth; and we should not indeed expect any marks of that disorderly prematureness of talent, which is so often fallacious, in a character whose distinguishing praise was to be regular and natural. His classical instruction was probably small, such as the private tutor of a Virginian country gentleman could at that period have imparted; and if his opportunities of information had been more favourable, the time was too short to profit by them (A). Before he was twenty he was appointed a major in the colonial militia, and he had very early occasion to display those political and military talents, of which the exertions on a greater theatre have since made his name so famous throughout the world.

The plenipotentiaries who framed the treaty of Aix la Chapelle, by leaving the boundaries of the British and French territories in North America unfixed, had sown the seeds of a new war, at the moment when they concluded a peace. The limits of Canada and Louisiana, negligently described in vague language by the treaties of Utrecht and Aix la Chapelle, because the greater part of these vast countries was then an impenetrable wilderness, furnished a motive, or a pretext, for one of the most successful, but one of the most bloody and wasteful wars in which Great Britain had ever been engaged. See BRITAIN, *Encycl.*

In the disputes which arose between the French and English officers on this subject. Major Washington was employed by the governor of Virginia, in a negociation with the French governor of Fort du Quesne (now Pitsburgh); who threatened the English frontiers with a body of French and their Indian allies. He succeeded in averting the invasion; but hostilities becoming inevitable, he was in the next year appointed lieutenant colonel of a regiment raised by the colony for its own defence; to the command of which he soon after succeeded. The expedition of Braddock followed in the year

(A) Several accounts of the life of Washington have stated that he served as a midshipman on board a British frigate. This is a mistake. His elder brother, who died young, served in that capacity in Vernon's expedition against Carthagena; whence the family seat was called Mount Vernon. Washington himself never left the United States, except in one short voyage to a West India island, when he was very young.

year 1755; of which the fatal issue is too well known to require being described by us. Colonel Washington served in that expedition only as a volunteer; but such was the general confidence in his talents, that he may be said to have conducted the retreat. Several British officers are still alive who remember the calmness and intrepidity which he shewed in that difficult situation, and the voluntary obedience which was so cheerfully paid by the whole army to his superior mind. After having acted a distinguished part in a subsequent and more successful expedition to the Ohio, he was obliged by ill health, in the year 1758, to resign his military situation. The fixteen years which followed of the life of Washington supply few materials for the biographer. Having married Mrs Custis, a Virginian lady of amiable character and respectable connections, he settled at his beautiful seat of Mount Vernon, of which we have had so many descriptions; where, with the exception of such attendance as was required by his duties as a magistrate and a member of the assembly, his time was occupied by his domestic enjoyments, and the cultivation of his estate, in a manner well suited to the tranquillity of his pure and unambitious mind. At the end of this period he was called by the voice of his country from this state of calm and secure though unostentatious happiness.

For almost half a century symptoms of disaffection to the mother country had been so visible in the New England provinces, that so early as 1734 the celebrated Bishop Berkeley had predicted a total separation of North America from Great Britain. That prelate, when a private clergyman, had lived three years in Rhode Island, and was an attentive and sagacious observer of the manners and principles of the people, among whom he perceived the old leaven of their forefathers fermenting even then with great violence. The middle and southern provinces, however, were more loyal, and their influence, together with perpetual dread of the French before the peace of 1763, put off the separation to a more distant day than that at which, we have reason to believe, the Bishop expected it to take place. Virginia, the most loyal of all the colonies, had long been in the habit of calling itself, with a kind of proud pre-eminence, *his Majesty's ancient dominion*; and it was with some difficulty that the demagogues of New England could gain over that province when the time arrived for effecting their long meditated revolt. At last, however, they succeeded; and we find Mr Washington as a delegate from Virginia in the Congress which met at Philadelphia on the 26th of October 1774. (See America, n° 174. *Encycl.*) As no American united in so high a degree as he did, military experience with respectability of character, he was appointed to the command of the army which had assembled in the New England provinces, to hold in check the British army which was then encamped under General Gage at Boston.

At this period there is some reason to believe that neither Mr Washington nor his constituents entered heartily into the views of the New Englanders; but afraid lest the army of those rebellious fanatics, after shaking off the yoke of Great Britain, might give law to the continent, he took upon himself the command of that army in the month of July 1775 (n). To detail his conduct in the years which followed, would be to relate the history of the American war, which we have already related in the article America (*Encycl.*). Within a very short period after the declaration of independence, the affairs of America were in a condition so desperate, that perhaps nothing but the *peculiar* character of Washington's genius could have retrieved them. Activity was the policy of invaders. In the field of battle the superiority of a disciplined army is displayed. But delay was the wisdom of a country defended by undisciplined soldiers against an enemy who must be more exhausted by time than he could be weakened by defeat. It required the consummate prudence, the calm wisdom, the inflexible firmness, the moderate and well-balanced temper of Washington to embrace such a plan of policy, and to persevere in it: to resist the temptations of enterprize; to fix the confidence of his soldiers without the attraction of victory; to support the spirit of the army and the people amidst those slow and cautious plans of defensive warfare which are more dispiriting than defeat itself; to contain his own ambition and the impetuosity of his troops; to endure temporary obscurity for the salvation of his country, and for the attainment of solid and immortal glory; and to suffer even temporary reproach and obloquy, supported by the approbation of his own conscience and the applause of that small number of wise men, whose praise is an earnest of the admiration and gratitude of posterity. Victorious generals easily acquire the confidence of their army. Theirs, however, is a confidence in the *fortune* of their general. That of Washington's army was a confidence in his *wisdom*. Victory gives spirit to cowards, and even the agitations of defeat sometimes impart a courage of despair. Courage is inspired by success, and it may be stimulated to desperate exertion even by calamity; but it is generally palsied by inactivity.—A system of cautious defence is the severest trial of human fortitude; and by this test the firmness of Washington was tried. It must not, however, be concealed, that some of the British commanders gave him advantages, which he surely did not expect; for more than once, as it appears to us, they had it in their power to annihilate his army, merely by following up their victories. The issue of the contest is known.

Much has been said by the British and American democrates of the magnanimity of Washington during the ravages of a civil war, in which he acted so conspicuous a part; and we feel not ourselves inclined to refuse him the praise which he may have merited on this or on any other account. But granting that duty required him to execute as a spy the accomplished *André*, true magnanimity would have prevented him from insultingly erecting, in the view of that unfortunate officer, the gallows on which he was to be hung, several days

(n) That such were the motives of his conduct on this occasion, is rendered in the highest degree probable in the preface to *A View of the Causes and Consequences of the American Revolution, in thirteen Discourses, Preached in North America, between the years* 1763 and 1775; by Jonathan Boucher, A. M. and F. A. S. Vicar of Epsom in the County of Surrey.

days before his execution! When Earl Cornwallis was overpowered by numbers, and obliged at York-town to surrender to the united armies of America and France, a magnanimous conqueror would not have maliciously claimed, contrary to the usage of civilized war, the sword from the hands of that gallant nobleman. On these two occasions, and on some others, the conduct of Washington agreed so ill with his general character, that we are inclined to believe that he must have been influenced by the leaders of the French army Rochembeau and Fayette. One thing is certain, that he was so little pleased either with his own conduct on particular occasions, or with the general principle of the American revolution, that he never could be forced to talk on the subject. An Italian nobleman, who visited him after the peace, had often attempted, in vain, to turn the conversation to the events of the war. At length he thought he had found a favourable opportunity of effecting his purpose; they were riding together over the scene of an action where Washington's conduct had been the subject of no small animadversion. Count ——— said to him, "Your conduct, Sir, in this action has been criticised." Washington made no answer, but clapped spurs to his horse; after they had passed the field, he turned to the Italian and said, "Count ———, I observe that you wish me to speak of the war; it is a conversation which I always avoid. I rejoice at the establishment of the liberties of America. But the time of the struggle was a horrible period, in which the best men were compelled to do many things repugnant to their nature." This, we think, is the language of a good man not altogether satisfied with the part which he had been compelled to act, and who though he rejoiced at the establishment of the *liberties* of America, probably foresaw that she would reap no benefit from her favourite *independence*.

The conclusion of the American war permitted Washington to return to those domestic scenes, from which no views of ambition seem to have had the power to draw him. But he was not allowed long to enjoy this privacy. The supreme government of the United States, hastily thrown up, in a moment of turbulence and danger, as a temporary fortification against anarchy, proved utterly inadequate to the preservation of general tranquillity and permanent security. The confusions of civil war had given a taint to the morality of the people, which rendered the restraints of a just and vigorous government more indispensably necessary. Confiscation and paper money, the two greatest schools of rapacity and dishonesty in the world, had widely spread their poison among the Americans. One of their own writers tells us, that the whole system of paper money was a system of public and private frauds. In this state of things, which threatened the dissolution of morality and government, good men saw the necessity of concentrating and invigorating the supreme authority. Under the influence of this conviction, a convention of delegates was assembled at Philadelphia, which strengthened the bands of the Federal Union, and bestowed on Congress those powers which were necessary for the purposes of good government. Washington was the president of this convention, as he, in three years after, was elected president of the United States of America, under what was called "The New Constitution," tho' it ought to have been called a *reform* of the republican government, as that republican government itself was only a *reform* of the ancient colonial constitution under the British crown. None of these changes extended so far as an attempt to new-model the whole social and political system.

Events occurred during his chief magistracy which convulsed the whole political world, and which tried most severely his moderation and prudence. The French revolution took place; Washington, who had experienced the evils of one revolution, augured, from the beginning, no good from the daring speculations of inexperienced visionaries; and the progress of the revolution was not calculated to cure his distrust. When, in the year 1793, France, then groaning under the most intolerable and hideous tyranny, became engaged in war with almost all the governments of the civilized world, it is said to have been a matter of deliberation with the President of the United States, whether the republican envoy, or the agent of the French princes should be received in America as the diplomatic representative of France. But whatever might be his private feelings of repugnance and horror, his public conduct was influenced only by his public duties. As a virtuous man he must have abhorred the system of crimes which was established in France. But as the first magistrate of the American commonwealth, he was bound only to consider how far the interest and safety of the people whom he governed were affected by the conduct of France. He saw that it was wise and necessary for America to preserve a good understanding and a beneficial intercourse with that great country, in whatever manner she was governed, as long as she abstained from committing injury against the United States. Guided by this just and simple principle, uninfluenced by the abhorrence of crimes which he felt, and which others affected, he received Mr Genet, the minister of the French Republic. The history of the outrages which that minister committed, or instigated, or countenanced, against the American government, must be fresh in the memory of all our readers. The conduct of Washington was a model of firm and dignified moderation. Insults were offered to his authority in official papers, in anonymous libels, by incendiary declaimers, and by tumultuous meetings. The law of nations was trampled under foot. His confidential ministers were seduced to betray him, and the deluded populace were so inflamed by the arts of their enemies, that they broke out into insurrection. No vexation, however galling, could disturb the tranquillity of his mind, or make him deviate from the policy which his situation prescribed. With a more confirmed authority, and at the head of a longer established government, he might perhaps have thought greater vigour justifiable. But in his circumstances, he was sensible that the nerves of authority were not strong enough to bear being strained. Persuasion, always the most desirable instrument of government, was in his case the safest. Yet he never overpassed the line which separates concession from meanness. He reached the utmost limits of moderation, without being betrayed into pusillanimity. He preserved external and internal peace by a system of mildness, without any of those virtual confessions of weakness, which so much dishonour and enfeeble supreme authority. During the whole of that arduous struggle, his personal character gave that strength to a *new magistracy* which in other countries ...

ancient habits of obedience and respect. The authority of his virtue was more efficacious for the preservation of America than the legal powers of his office.

During this turbulent period, he was re-elected to the office of the Presidency of the United States, which he held from April 1789 till September 1796. Probably no magistrate of any commonwealth, ancient or modern, ever occupied a place so painful and perilous. Certainly no man was ever called upon so often to sacrifice his virtuous feelings (he had no other sacrifices to make) to his public duty. Two circumstances of this sort deserve to be particularly noticed. In the spring of 1794, he sent an ambassador to Paris with credentials, addressed to his "Dear friends the citizens composing the Committee of Public Safety of the French Republic," whom he prays God "to take under his holy protection." Fortunately the American ambassador was spared the humiliation of presenting his credentials to these bloody tyrants. Their power was subverted, and a few of them had suffered the punishment of their crimes, which no punishment could expiate, before his arrival at Paris. Readily as we admit the purity of the motives which induced him to send this embassy to Paris, we cannot possibly approve of his conduct in deviating so far from the usual diplomatic style, as to call Robespierre his friend: but he was beset by an absurd, though formidable, faction at home.

He had another struggle of feeling and duty to encounter, when he was compelled to suppress the insurrection in the western counties of Pennsylvania by force of arms. But here he had a consolation. The exercise of mercy consoled his mind for the necessity of having recourse to arms. Never was there a revolt quelled with so little blood. Scarcely ever was the basest dastard so tender of his own life, as this virtuous man was of the lives of his follow citizens. The value of his clemency is enhanced by recollecting that he was neither without provocations to severity, nor without pretexts for it. His character and his office had been reviled in a manner almost unexampled among civilized nations. His authority had been insulted.—His safety had been threatened. Of his personal and political enemies some might, perhaps, have been suspected of having instigated the insurrection; a greater number were thought to wish well to it; and very few shewed much zeal to suppress it. *Is habitus animorum fuit, ut pessimum facinus auderent pauci, plures vellent, omnes paterentur.* But neither resentment, nor fear, nor even policy itself, could extinguish the humanity of Washington. This seems to have been the only sacrifice which he was incapable of making to the interest of his country.

Throughout the whole course of his second Presidency, the danger of America was great and imminent almost beyond example. The spirit of change, indeed, at that period, shook all nations. But in other countries it had to encounter ancient and solidly established power; it had to tear up by the roots long habits of attachment in some nations for their government; of awe in others; of acquiescence and submission in all.—But in America the government was new and weak. The people had scarce time to recover from the ideas and feelings of a recent civil war. In other countries the volcanic force must be of power to blow up the mountains, and to convulse the continents that held it down, before it could escape from the deep caverns in which it was imprisoned:—in America it was covered only by the ashes of a late convulsion, or at most by a little thin soil, the produce of a few years quiet.

The government of America had none of those salutary prejudices to employ, which in every other country were used with success to open the eyes of the people to the enormities of the French revolution. They had, on the contrary, to contend with the prejudices of their people in the most moderate precautions against internal confusion, in the most measured and guarded resistance to the unparalleled insults and enormous encroachments of France. Without zealous support from the people, the American government was impotent. It required a considerable time, and it cost an arduous and dubious struggle, to direct the popular spirit against a sister republic, established among a people to whose aid the Americans ascribed the establishment of their independence. It is probable, indeed, that no policy could have produced this effect, unless it had been powerfully aided by the crimes of the French government, which have proved the strongest allies of all established governments; which have produced such a general disposition to submit to any *known* tyranny, rather than rush into all the unknown and undefinable evils of civil confusion, with the horrible train of new and monstrous *tyrannies* of which it is usually the forerunner. But of these circumstances Washington availed himself with uncommon address. He employed the horror excited by the atrocities of the French revolution for the most honest and praise-worthy purposes; to preserve the internal quiet of his country; to assert the dignity, and to maintain the rights, of the commonwealth which he governed, against foreign enemies. He avoided war without incurring the imputation of pusillanimity. He cherished the detestation of Americans for anarchy, without weakening the spirit of liberty; and he maintained, and even consolidated, the authority of government, without abridging the privileges of the people.

The resignation of Washington in 1796 was certainly a measure of prudence, and we doubt not of patriotism; but the conduct of his successor has been such as to give the Americans reason to regret that the reins of government were thrown up by the only hand, perhaps, that was fit to guide them during so unsettled a state of public affairs. When he retired, he published a valedictory address to his countrymen, as he had before done when he quitted the command of the army in 1783. In these compositions, the whole heart and soul of Washington are laid open. Other state papers have, doubtless, shewn more spirit and dignity, more eloquence, greater force of genius, and a more enlarged comprehension of mind; but none ever displayed more simplicity and ingenuousness, more moderation and sobriety, more good sense, more prudence, more honesty, more earnest affection for his country and for mankind, more profound reverence for virtue and religion; more ardent wishes for the happiness of his fellow-creatures, and more just and rational views of the means which alone can effectually promote that happiness.

From his resignation till the month of July 1798, he lived in retirement at Mount Vernon. At this latter period, it became necessary for the United States to arm. They had endured with a patience, of which there is no example in the history of states, all the contumely

Washington, Watchwork.

tunely and wrong which successive administrations in France had heaped upon them. Their ships were everywhere captured, their ministers were detained in a fort of imprisonment at Paris; while incendiaries, clothed in the sacred character of ambassadors, scattered over their peaceful provinces the fire brands of sedition and civil war. An offer was made to terminate this long course of injustice, for a bribe to the French ministers. This offer was made by persons who *appeared* to be in the confidence of M. Talleyrand, who *professed* to act by his authority; who have been since, indeed, disavowed by him; but who never will be believed not to have been his agents, till he convict them of imposture by legal evidence, and procure them to be punished for so abominable a fraud.

The United States resolved to arm by land and sea. The command of the army was bestowed on General Washington; which he accepted, because he was convinced that "every thing we hold dear and sacred was seriously threatened*;" though he had flattered himself "that he had quitted for ever the boundless field of public action, incessant trouble and high responsibility, in which he had long acted so conspicuous a part." In this office he continued during the short period of his life which still remained.—On Thursday the 12th December 1799, he was seized with an inflammation in his throat, which became considerably worse the next day; and of which, notwithstanding the efforts of his physicians, he died on Saturday the 14th of December 1799, in the 68th year of his age, and in the 23d year of the independence of the United States, of which he may be considered as the founder. The same calmness, simplicity, and regularity, which had uniformly marked his demeanor, did not forsake him in his dying moments. He saw the approaches of death without fear: —he met them without parade.—Even the perfectly well-ordered state of the most minute particulars of his private business, bore the stamp of that constant authority of prudence and practical reason over his actions, which was a distinguishing feature of his character. He died with those sentiments of piety which had given vigour and consistency to his virtue, and adorned every part of his illustrious life.

* See his *Letter of Acceptance*.

WATCHWORK. Our intention in this article does not extend to the manual practice of this art, nor even to all the parts of the machine We mean to consider the most important and difficult part of the construction, namely, the method of applying the maintaining power of the wheels to the regulator of the motion, so as not to hurt its power of regulation. Our observations would have come with more propriety under the title SCAPEMENT, that being the name given by our artists to this part of the construction. Indeed they were intended for that article, which had been unaccountably omitted in the body of the Dictionary under the words CLOCK and WATCH. But the bad health and occupations of the person who had engaged to write the article, have obliged us to defer it to the last opportunity which the alphabetical arrangement affords us; and, even now, the same causes unfortunately prevent the author from treating the subject in the manner he intended, and which it well deserves. But we trust that, from the account which is here given, the reader, who is conversant in mathematical philosophy, will perceive the justness of the conclusions, and that an intelligent artist will have no hesitation in acceding to the propriety of the maxims of construction deduced from them.

The regulator of a clock or watch is a pendulum or a balance. Without this check to the motion of the wheels, impelled by a weight or a spring, the machine would run down with a motion rapidly accelerating, till friction and the resistance of the air induced a sort of uniformity, as they do in a kitchen jack. But if a pendulum be so put in the way of this motion, that only one tooth of a wheel can pass it at each vibration, the revolution of the wheels will depend on the vibration of the pendulum. This has long been observed to have a certain constancy, insomuch that the astronomers of the East employed pendulums in measuring the times of their observations, patiently counting their vibrations during the phases of an eclipse or the transits of the stars, and renewing them by a little push with the finger when they became too small Gassendi, Riccioli, and others, in more recent times, followed this example. The celebrated physician Sanctorius is the first person who is mentioned as having applied them as regulators of clock movements. Machines, however, called *clocks*, with a train of toothed wheels, leading round an index of hours, had been contrived long before. The earliest of which we have any account is that of Richard of Wallingford, Abbot of St Alban's, in 1326 (A). It appears to have been regulated by a fly like a kitchen jack*. Not long after this Giacomo Dondi made one at Padua, which had a *motus succussorius*, a hobbling or trotting motion; from which expression it seems probable that it was regulated by some alternate movement. We cannot think that this was a pendulum, because, once it was introduced, it never could have been supplanted by a balance. The alternate motion of a pendulum, and its seeming uniformity, are among the most familiar observations of common life; and it is surprising that they were not more early thought of for regulating time measurers. The alternate motions of the old balance is one of the most far-fetched means that can be imagined, and might pass for the invention of a very reflecting mind, while a pendulum only requires to be drawn aside from the plumb-line, to make it vibrate with regularity. The balance must be put in motion by the clock, and that motion must be stopped, and the contrary motion induced; and we must know that the same force and the same checks will produce uniform oscillations. All this must be previously known before we can think of it as a regulator; yet so it is that clocks, regulated by a balance, were long used, and very common through Europe, before Galileo proposed the pendulum, about the year 1600. Pendulum clocks then came into general use, and were found to be greatly preferable to balance clocks as accurate measurers of time. Mathematicians saw that their vibrations had some regular-

* [illegible]

(A) Professor Beckmann, in the first volume of his *History of Inventions*, expresses a belief that clocks of this kind were used in some monasteries so early as the 11th century, and that they were derived to the monks from the Saracens. His authorities, however, are discordant, and seem not completely satisfactory even to himself.

Watch-work.

gular dependence on uniform gravity, and in their writings we meet with many attempts to determine the time and demonstrate the isochronism of the vibrations. It is amusing to read these attempts. We wonder at the awkwardness and insufficiency of the explanation given of the motions of pendulums, even by men of acknowledged eminence. Mersennus carried on a most useful correspondence with all the mathematicians of Europe, and was the means of making them acquainted with each other; nay, he was himself well conversant in the science; yet one cannot but smile at his reasonings on this subject. Standing on the shoulders of our predecessors, we look around us, in great satisfaction with our own powers of observation, not thinking how we are raised up, or that we are trading with the stock left us by the diligent and sagacious philosophers of the 17th century (B). Riccioli, Gassendus, and Galileo, made similar attempts to explain the motion of pendulums; but without success. This honour was reserved for Mr Huyghens, the most elegant of modern geometers. He had succeeded in 1656 or 1657 in adapting the machinery of a clock to the maintaining of the vibrations of a pendulum. Charmed with the accuracy of its performance, he began to investigate with scrupulous attention the theory of its motion. By the most ingenious and elegant application of geometry to mechanical problems, he demonstrated that the wider vibrations of a pendulum employed more time than the narrower, and that the time of a semicircular vibration is to that of a very small one nearly as 34 to 29; and, aided by a new department of geometrical science invented by himself, namely, the evolution of curves, he shewed how to make a pendulum swing in a cycloid, and that its vibrations in this curve are all performed in equal times, whatever be their extent.

But before this time, Dr Hooke, the most ingenious and inventive mechanician of his age, had discovered the great accuracy of pendulum clocks, having found that the manner in which they had been employed had obscured their real merit. They had been made to vibrate in very large arches, the only motion that could be given them by the contrivances then known; and in 1656 he invented another method, and made a clock which moved with astonishing regularity. Using a heavy pendulum, and making it swing in very small arches, the clocks so constructed were found to excel Mr Huyghens's cycloidal pendulums; and those who were unfriendly to Huyghens had a sort of triumph on the occasion. But this was the result of ignorance. Mr Huyghens had shewn, that the error of $\frac{1}{100}$ of an inch, in the formation of the parts which produced the cycloidal motion, caused a greater irregularity of vibration than a circular vibration could do, although it should extend five or six degrees on each side of the perpendicular. It has been found that the unavoidable inaccuracies, even of the best artists, in the cycloidal construction, make the performance much inferior to that of a common pendulum vibrating in arches which do not exceed three or four degrees from the perpendicular. Such clocks alone are now made, and they exceed all expectation.

We have said that a pendulum needed only to be removed from the perpendicular, and then let go, in order to vibrate and measure time. Hence it might seem, that nothing is wanted but a machinery so connected with the pendulum as to keep a register, as it were, of the vibration. It could not be difficult to contrive a method of doing this; but more is wanted. The air must be displaced by the pendulum. This requires some force, and must therefore employ some part of the momentum of the pendulum. The pivot on which it swings occasions friction—the thread, or thin piece of metal by which it is hung, in order to avoid this friction, occasions some expenditure of force by its want of perfect flexibility or elasticity. These, and other causes, make the vibrations grow more and more narrow by degrees, till at last the pendulum is brought to rest. We must therefore have a contrivance in the wheelwork which will restore to the pendulum the small portion of force which it loses in every vibration. The action of the wheels therefore may be called a *maintaining power*, because it keeps up the vibrations.

But we now see that this may affect the regularity of vibration. If it be supposed that the action of gravity renders all the vibrations isochronous, we must grant that the additional impulsion by the wheels will destroy that isochronism, unless it be so applied that the sum total of this impulsion and the force of gravity may vary so with the situation of the pendulum, as still to give a series of forces, or a law of variation, perfectly similar to that of gravity. This cannot be effected, unless we know both the law which regulates the action of gravity, producing isochronism of vibration, and the intensity of the force to be derived from the wheels in every situation of the pendulum.

The necessary requisite for the isochronous motion of the pendulum is, that the force which urges it toward the perpendicular, be proportional to its distance from it (see DYNAMICS, n° 103. Cor. 7. *Suppl.*); and therefore, since pendulums swinging in small circular arches are sensibly isochronous, we must infer that such is the law by which the accelerating action of gravity on them is really accommodated to every situation in those arches.

It will greatly conduce to the better understanding of the effect of the maintaining power, if the reader keep in continual view the chief circumstances of a motion of this kind. Therefore let AC*a* (fig. 1.) represent the arch passed over by the pendulum, stretched out into a straight line. Let C be its middle point, when the pendulum hangs perpendicular, and A and *a* be the extremities of the oscillation. Let AD be drawn perpendicular to AC, to represent the accelerating action of gravity on the pendulum when it is at A. Draw the straight line DC*d*, and *ad*, perpendicular to A*a*. About C, as a centre, describe the semicircle AFH*a*. Through

Plate XLVIII.

(B) We are provoked to make this observation, by observing at this moment, in a literary journal, a pert and petulant upstart speaking of Newton's optical discoveries in terms of ridicule and abuse, employing these very discoveries to diminish his authority. Is it not thus that Christianity is now slighted by those who enjoy the fruits of the pure morality which it introduced?

Through any points B, K, *k*, *b*, &c. of A *a*, draw the perpendiculars BFE, KLM, &c. cutting both the straight line and the semicircle. Then,

1. The actions of gravity on the pendulum, when in the situations B, K, &c. by which it is urged toward C, are proportional to, and may be represented by, the ordinates BE, KL, *be*, *kl*, &c. to the straight line DC *d*.

2. The velocities acquired at B, K, &c. by the acceleration along AB, AK, &c. are proportional to the ordinates BF, KM, &c. to the semicircle AH *a*; and, therefore, the velocity with which the pendulum passes through the middle point C, is to its velocity in any other point B, as CH to BF.

3. The times of describing the parts AB, BK, KC, &c. of the whole arch of oscillation, are proportional to, and may be represented by, the arches AF, FM, MH, &c. of the semicircle.

4. If one pendulum describe the arch represented by AC *a*, and another describe the arch KC *k*, they will describe them in equal times, and their maximum velocities (viz. their velocities in the middle point), are proportional to AC and KC; that is, the velocities in the middle point are proportional to the width of the oscillations.

The same proportions are true with respect to the motions outwards from C. That is, when the pendulum describes CA, with the initial velocity CH, its velocity at K is reduced to KM by the retarding action of gravity. It is reduced to BF at B, and to nothing at A; and the times of describing CK, KB, BA, CA, are as HM, HF, HA. Another pendulum setting out from C, with the initial velocity CO, reaches only to K, CK being = CO. Also the times are equal.—If we consider the whole oscillation as performed in the direction A *a*, the forces AD, BE, KL accelerate the pendulum, and the similar forces *a d*, *b e*, *k l*, on the other side, retard it. The contrary happens in the next oscillation *a*CA.

5. The areas DABE, DAKL, &c. are proportional to the squares of the velocities acquired by moving along AB, AK, &c. or to the diminution of the squares of the velocities sustained by moving outwards along BA or KA, &c.

The consideration of this figure will enable the reader (even though not a mathematician) to form some notion of the effect of any proposed application of a maintaining power by means of wheelwork: For, knowing the weight of the pendulum, we know the accelerating action of that weight in any particular situation A of the pendulum. We also know what addition or subtraction we produce on the pendulum in that situation by the wheel-work. Suppose it is an addition of pressure equal to a certain number of grains. We can make AD to D*δ* as the first to the last; and then A*δ* will be the whole force urging the pendulum toward C. Doing the same for every point of AC, we obtain a line *δ ε λ c*, which is a new scale of forces, and the space DC*δ*, comprehended between the two scales CD and C*δ*, will express the addition made to the square of the velocity in passing along AC by the joint action of gravity and the maintaining power. Also, by drawing a line *x π* perpendicular to AC, making the space C*π x* equal to CAD, the point *π* will be the limit of the oscillation outward from C, where the initial velocity HC is extinguished. If the line *x π* cut the same circle in *ς*, one-half the arch *ς* A will nearly express the contraction made in the time of the outward oscillation by the maintaining power. An accurate determination of this last circumstance is operose, and even difficult; but this solution is not far from the truth, and will greatly assist our judgment of the effect of any proposal, even though *x π* be drawn only by the judgement of the eye, making the area left out as nearly equal to the area taken in as we can estimate by inspection. This is said from experience.

Since the motion of a pendulum or balance is alternate, while the pressure of the wheels is constantly in one direction, it is plain that some art must be used to accommodate the one to the other. When a tooth of the wheel has given the balance a motion in one direction, it must quit it, that it may get an impulsion in the opposite direction. The balance or pendulum thus escaping from the tooth of the wheel, or the tooth escaping from the balance, has given to the general contrivance the name of SCAPEMENT among our artists, from the French word *echappement*. We proceed, therefore, to consider this subject more particularly, first considering the scapements which are peculiarly suited to the small vibrations of pendulums, and then those which must produce much wider vibrations in balances. This, with some other circumstances, render the scapements for pendulums and balances very different.

I. *Of the Action of a Wheel and Pallet.*

THE scapement which has been in use for clocks and watches ever since their first appearance in Europe, is extremely simple, and its mode of operation is too obvious to need much explanation. In fig. 2. XY represents a horizontal axis, to which the pendulum P is attached by a slender rod, or otherwise. This axis has two leaves C and D attached to it, one near each end, and not in the same plane, but so that when the pendulum hangs perpendicularly, and at rest, the piece C spreads a few degrees to the right hand, and D as much to the left. They commonly make an angle of 70, 80, or 90 degrees. These two pieces are called PALLETS. AFB represents a wheel, turning round on a perpendicular axis EO, in the order of the letters AFEB. The teeth of this wheel are cut into the form of the teeth of a saw, leaning forward, in the direction of the motion of the rim. As they somewhat resemble the points of an old fashioned royal diadem, this wheel has got the name of the CROWN WHEEL. In watches it is often called the *balance wheel*. The number of teeth is generally odd; so that when one of them B is pressing on a pallet D, the opposite pallet C is in the space between two teeth A and I. The figure represents the pendulum at the extremity of its excursion to the right hand, the tooth A having just escaped from the pallet C, and the tooth B having just dropped on the pallet D. It is plain, that as the pendulum now moves over to the left, in the arch PG, the tooth B *continues* to press on the pallet D, and thus accelerates the pendulum, both during its descent along the arch PH, and its ascent along the arch HG. It is no less evident, that when the pallet D by turning round the axis XY, raises its point above the plane of the wheel, the tooth B escapes from it, and I drops on the pallet C, which is now nearly perpendicular. I presses C to the right, and

and accelerates the motion of the pendulum along the arch GP. Nothing can be more obvious than this action of the wheel in maintaining the vibrations of the pendulum. We can easily perceive, also, that when the pendulum is hanging perpendicularly in the line XH, the tooth B, by pressing on the pallet D, will force the pendulum a little way to the left of the perpendicular, and will force it so much the farther as the pendulum is lighter; and, if it be sufficiently light, it will be forced so far from the perpendicular that the tooth B will escape, and then I will catch on C, and force the pendulum back to P, where the whole operation will be repeated. The same effect will be produced in a more remarkable degree, if the rod of the pendulum be continued through the axis XY, and a ball Q put on the other end to balance P. And, indeed, this is the contrivance which was first applied to clocks all over Europe, before the application of the pendulum. They were balance clocks. The force of the wheel was of a certain magnitude, and therefore able, during its action on a pallet, to communicate a certain quantity of motion and velocity to the balls of the balance. When the tooth B escapes from the pallet D. the balls are then moving with a certain velocity and momentum. In this condition, the balance is checked by the tooth I catching on the pallet C. But it is not instantly stopped. It continues its motion a little to the left, and the pallet C forces the tooth I a little backward. But it *cannot* force it so far as to escape over the top of the tooth I; because all the momentum of the balance was generated by the force of the tooth B; and the tooth I is equally powerful. Besides, when I catches on C, and C continues its motion to the left, its lower point applies to the face of the tooth I, which now acts on the balance by a long and powerful lever, and soon stops its farther motion in that direction, and now, continuing to press on C, it urges the balance in the opposite direction.

Thus we see that in a scapement of this kind, the motion of the wheel must be very hobbling and unequal, making a great step forward, and a short step backward, at every beat. This has occasioned the contrivance to get the name of the RECOILING SCAPEMENT, the recoiling pallets. This hobbling motion is very observable in the wheel of an alarm.

Thus have we obtained two principles of regulation. The first and most obvious, as well as the most perfect, is the natural isochronous vibration of a pendulum. The only use of the wheelwork here, besides registering the vibrations, is to give a gentle impulsion to the pendulum, by means of the pallet, in order to compensate friction, &c. and thus maintain the vibrations in their primitive magnitude. But there is no such native motion in a balance, to which the motion of the wheels must accommodate itself. The wheels, urged by a determined pressure, and acting through a determined space (the face of the pallet), must generate a certain determined velocity in the balance; and therefore the time of the oscillation is also determined, both during the progressive and the retrograde motion of the wheel. The actions being similar, and through equal spaces, in every oscillation, they must employ the same time. Therefore a balance, moved in this manner, must be isochronous, and a regulator for a time-keeper.

By thus employing a balance, the horizontal position of the axis XY is unnecessary. Accordingly, the old clocks had this axis perpendicular, by which means the whole weight of the balance rested on the point of the pivot Y or X, according as the balance PQ was placed above or below. By making the supporting pivot of hard steel, and very sharp, friction was greatly diminished. Nay, it was entirely removed from this part of the machine by suspending the balance by a thread at the end X instead of allowing it to rest on the point of the pivot Y.

As the balance regulator of the motion admits of every position of the machine, those clocks were made in an infinite variety of fanciful forms, especially in Germany, a country famous for mechanical contrivances. They were made of all sizes, from that of a great steeple clock, to that of an ornament for a lady's toilet. The substitution of a spring in place of a weight, as a first mover of the wheel-work, was a most ingenious thought. It was very gradual. We have seen, in the Emperor's museum at Brussels, an old (perhaps the first) spring clock, the spring of which was an old sword blade, from the point of which a catgut was wound round the barrel of the first wheel. Some ingenious German substituted the spiral spring, which both took less room, and produced more revolutions of the first wheel.

When clocks had been reduced to such small sizes, the wish to make them portable was very natural; and the means of accomplishing this were obvious, namely, a farther reduction of their size. This was accomplished very early; and thus we obtained pocket watches, moved by a spiral spring, and regulated by a balance with the recoiling scapement, which is still in use for common watches. The hobbling motion of the crown wheel is very easily seen in all of them.

It is very uncertain who first substituted a pendulum in place of the balance (CLOCK, *Encycl.*) Huyghens, as we have already observed, was the first who investigated the motions of pendulums with success, and his book *De Horologio Oscillatorio* may be considered as the elements of refined mechanics, and the source of all the improvements that have been made in the construction of scapements. But it is certain that Dr Hooke had employed a pendulum for the regulation of a clock many years before the publication of the abovementioned treatise, and he claims the merit of the invention of the *only proper* method of employing it. We imagine therefore that Dr Hooke's invention was nothing more than a scapement for a pendulum making small vibrations, without making use of the opposite motions of the two sides of the crown wheel. Dr Hooke had contrived some scapement more proper for pendulums than the recoiling pallets, because certainly those might be employed, and are actually employed as a scapement for pendulum clocks to this day, although they are indeed very ill adapted to the purpose. He had not only remarked the great superiority of such pendulum clocks as were made before Huyghens's publication of the cycloidal pendulum over the balance clocks, but had also seen their defects, arising from the light pendulums and wide arches of vibration, and invented a scapement of the nature of those now employed. The pendulum clock which he made in 1658 for Dr Wilkins afterwards Bishop of Chester, is mentioned by the inventor as peculiarly suited to the moderate swing of a pendulum; and he opposes this circumstance to a general

practice

practice of wide vibrations and trifling pendulums. The French are not in the practice of ascribing to us any thing that they can claim as their own; yet Lepaute says that the *Echappement à l'Ancre* came from England about the year 1665. It is also admitted by him that clock-making flourished in England at that time, and that the French artists went to London to improve in it. Putting these and other circumstances together, we think it highly probable that we are indebted to Dr Hooke for the scapement now in use. The principle of this is altogether different from the simple pallets and direct impulse already described; and is so far from being obvious, that the manner of action has been misunderstood, even by men of science, and writers of systems of mechanics.

In this scapement we employ those teeth of the wheel which are moving in one direction; whereas in the former scapement, opposite teeth were employed moving in contrary directions. Yet even here we must communicate an alternate motion to the axis of the pallets. The contrivance, in general, was as follows: On the axis A (See fig. 3) of the pendulum or balance is fixed a piece of metal BAC, called the CRUTCH by our artists, and the ANCHOR by the French. It terminates in two faces B *b* C *c* of tempered steel, or of some hard stone. These are called the PALLETS, and it is on them that the teeth of the wheel act. The faces B *b* C *c* are set in such positions that the teeth push them out of the way. Thus B pushes the pallet to the left, and C pushes its pallet to the right. Both push their pallets sidewise outward from the centre of the wheel. The pallet B is usually called the *leading*, and C the *driving* pallet by the artists, although it appears to us that these names should be reversed, because B *drives* the pallet out of the way, and C *pulls* or leads it out of the way. They might be called the *first* and *second* pallet, in the order in which they are acted on by the wheel. We shall use either denomination. The figure is accommodated to the inactive or resting position of the pendulum. Suppose the pendulum drawn aside to the right at Q, and then let go. It is plain that the tooth B, pressing on the face of the pallet β B *b* all the way from β to *b*, thrusts it aside outwards, and thus, by the connection of the crutch with the pendulum rod, aids the pendulum's motion along the arch QPR. When the pendulum reaches R, the point of the tooth B has reached the angle *b* of the pallet, and escapes from it. The wheel pressing forward, another tooth C drops on the pallet face C *c*, and, by pressing this pallet outward, evidently aids the pendulum in its motion from R to P. The tooth C escapes from this pallet at the angle *c*, and now a tooth B′ drops on the first pallet, and again aids the pendulum; and this operation is repeated continually.

The mechanism of this communication of motion is thus explained by several writers of elements. The tooth B (fig. 2.) is urged forward in the direction BD, perpendicular to the radius MB of the SWING WHEEL. It therefore presses on the pallet, which is moveable only in the direction BE, perpendicular to BA the radius of the pallet. Therefore the force BD must be resolved into two, *viz.* BE, in the direction in which alone the pallet can move, and ED, or BF, perpendicular to that direction. The last of these only presses the pallet and crutch against the pivot hole A. BE is the only useful force, or the force communicated to the pallet, enabling it to maintain the pendulum's motion, by restoring the momentum lost by friction and other causes.

But this is a very erroneous account of the *modus operandi*, as may be seen at once, by supposing the radius of the pallets to be a tangent to the wheel. This is a position most frequently given to them, and is the very position in fig. 3. In this case MB is perpendicular to BA, and therefore BD will coincide with BA, and there will be no such force as BE to move the pendulum. It is a truth, deducible from what we know of the mechanical constitution of solid bodies, and confirmed by numberless observations, that when two solid bodies press on each other, either in impulsion or in dead pressure, the direction in which the mutual pressure is excited is always perpendicular to the touching surfaces, whatever has been the direction of the impelling body (See IMPULSION, *Suppl.* n° 66. MACHINERY, *Suppl.* n° 35. and several other parts of this Work) Moreover this pressure is mutual, equal, and opposite. Whatever be the shapes of the faces of the tooth and pallet, we can draw a plane BN, which is the common tangent to both surfaces, and a line HBI through the point of contact perpendicular to BN. It is farther demonstrated in the article MACHINERY, *Suppl.* n° 35. &c. that the action of the wheel on the pendulum is the same as if the whole crutch were annihilated, and in its stead there were two rigid lines AH, MI, from the centres of the crutch and wheel, perpendicular to HI, and connected by a third rigid line or rod HI, touching the two in H and I.

For if a weight V be hung at *v*, the extremity of the horizontal radius M *v* of the wheel, it will act on the lever *v* MI, pressing its point I upwards in the direction IH perpendicular to MI; the upper end of this rod IH will, in like manner, press the extremity H of the rod HA, and this will urge the pendulum from P toward R. To withstand this, the pendulum rod AP may be withheld by a weight *z*, hanging by a thread on the extremity of the horizontal lever A *z*, equal to M *v*, and connected with the crutch and pendulum. The weights V and *z* may be so proportioned to each other that, by acting perpendicularly on the crooked levers *v* MI, and *z* AH, the pressures at H and I shall be equal, and just balance each other by the intervention of the rod HI. When this is the case, we have put things into the same mechanical state, in respect of mutual action, as is effected by the crutch, pallets, and wheel, which in like manner, produce equal pressures at B the point of contact, in the direction BH and BI. The weight V may be such as produces the very same effect at B that is produced by the previous train of wheel-work. The weight *z* therefore must be just equal to the force produced by the wheel-work on the point *z* of the pendulum rod, because by acting in the opposite direction it just balances it. Let us see therefore what force is communicated to the pendulum by the wheels.

Let *x* be the upward pressure excited at I, and *y* the equal opposite pressure excited at H. Then, by the property of the lever, we have $\text{MI} : \text{M}v = \text{V} : x$, and $x \times \text{MI} = \text{V} \times \text{M}v$. In like manner $y \times \text{AH} = \text{Z} \times \text{A}z$. Therefore, because $x = y$, and $\text{A}z = \text{M}v$, we have $\text{V} : \text{Z} = \text{MI} : \text{AH}$. That is, the force exerted

Watch-work.

ed by the tooth of the wheel in the direction of its motion is to the force impressed on the pendulum rod at a distance equal to the radius of the wheel as MI to AH. The force impressed on the ball of the pendulum is less than this in the proportion of AP to A z, or M v.

Cor. 1. If the perpendiculars MN, AV, be drawn on the tangent plane, the forces at B and z will be as BN to BO. For these lines are respectively equal to MI and AH.

Cor. 2. If HI meet the line of the centres AC in S, the forces will be as SM to SA; that is, V : Z = SM : SA.

Cor. 3. If the face β B b of the pallet be the evolutrix of a circle described with the radius AH, and the face of the tooth be the evolutrix of a circle described with the radius MI, the force impressed on the pendulum by the wheels will be constant during the whole vibration (MACHINERY, n° 36) But these are not the only forms which produce this constancy. The forms of teeth described by different authors, such as De la Hire. Camus, &c. for producing a constant force in trains of wheel-work, will have the same effect here. It is also easy to see that the force impressed on the pendulum may be varied according to any law, by making these faces of a proper form. Therefore the face, from B outwards, may be so formed that the force communicated to the pendulum by the wheels, during its descent from Q to P, may be in one constant proportion to the acceleration of gravity, and then the sum of the forces will be such as produce isochronous vibrations. If the inner part B b of the face be formed on the same principle, the difference of the forces will have the same law of variation. If the face β b be the evolutrix of a circle, and the tooth B terminate in a point gently rounded, or quite angular, the force on the pendulum will continually increase as the tooth slides from β to b. For the line AH continues of the same magnitude, and MI diminishes. The contrary will happen, if the pallet be a point, either sharp or rounded, and if the face of the tooth be the evolutrix now mentioned; for MI will remain the same, while AH diminishes. If the tooth be pointed, and β b be a straight line, the force communicated to the pendulum will diminish, while the tooth slides from β to b. For in this case AH diminishes and MI increases.

Cor 4. In general, the force on the pendulum is greater as the angle MB b increases, and as AB b diminishes.

Cor. 5. The angular velocity of the wheel is to that of the pendulum, in any part of its vibration, as AH to MI This is evident, because the rod IH moving (in the moment under consideration) in its own direction, the points H and I move through equal spaces, and therefore the angles at A and M must be inversely as the radii

All that has now been said of the first pallet AB may be applied to the second pallet AC

If the perpendiculars C s be drawn to the touching plane o C n, cutting AM in s, we shall have V : z = s M : s A, as in Cor. 2. And if the perpendiculars M i, A h, be drawn on C r, we have V : Z = M i : A h, as in the general theorem. The only difference between the action on the two pallets is, that if the faces of both are plain, the force on the pendulum increases during the whole of the action on the pallet C, whereas it diminishes during the progress of the tooth along the other pallet.

The reader will doubtless remark that each tooth of the wheel acts on both pallets in succession; and that, during its action on either of them, the pendulum makes one vibration Therefore the number of vibrations during one turn of the wheel is double the number of the teeth: consequently, while the tooth slides along one of the pallets, it advances half the space between two successive teeth; and when it escapes from the pallet, the other tooth *may* be just in contact with the other pallet. We say it *may* be so; in which case there will be no dropping of the teeth from pallet to pallet. This, however, requires very nice workmanship. and that every tooth be at precisely the same distance from its neighbour. Should the tooth which is just going to apply to a pallet chance to be a little too far advanced on the wheel, it would touch the pallet before the other had escaped. Thus, suppose that before B escapes from the point b of the pallet, the tooth C is in contact with the pallet CG, B cannot escape. Therefore when the pendulum returns from R towards Q, the pallet β b, returning along with it, will push back the tooth B of the wheel. It does this in opposition to the force of the wheel. Therefore, whatever motion the wheel had communicated to the pendulum, during its swing from P to Q, will now be taken from it again. The pendulum will not reach Q, because it had been aided in its motion from Q and had proceeded further than it would have done without this help. Its motion toward Q is further diminished by the friction of the pallet. Therefore it will now return again from some nearer point q, and will not go so far as in the last vibration, but will return through a still shorter arch: And this will be still more contracted in the next vibration, &c. &c. Thus it appears that if a tooth chances to touch the pallet before the escape of the other, the wheel will advance no farther, and soon after the pendulum will be brought to rest.

For such reasons it is necessary to allow one tooth to escape *a little before* the other reaches the pallet on which it is to act, and to allow a small drop of the teeth from pallet to pallet. But it is accounted bad workmanship to let the drop be considerable, and *close scapement* is accounted a mark of care and of good workmanship. It is evidently an advantage, because it gives a longer time of action on each pallet. This freeing the scapement cannot be accomplished by filing something from the face of the tooth; because this being done to all, the distance between them is diminished rather than augmented. The pallets must be first scaped as close as possible. This obliges the workman to be careful in making the teeth equidistant. Then a small matter is taken from the point of each pallet, by filing off the back b r of the pallet. The tooth will now escape before it has moved through half a space.

From all that has been said on this particular, it appears that the interval between the pallets must comprehend a certain number of teeth, and half a space more.

The first circumstance to be considered in contriving a scapement is the angular motion that is intended to be given to the pendulum during the action of the wheel. This is usually called the *angle of scapement*, or the *angle of action*. Having fixed on an angle *a* that we think proper,

proper, we muft fecure it by the pofition and form of the face of the pallets. Knowing the number of teeth in the fwing-wheel, divide 180° by this number, and the quotient is the angle *b* of the wheel's motion during one vibration of the pendulum. In the line AM, joining the centres of the crutch and wheel, make SM to SA, and *s* M to *s* A, as the angle *a* to the angle *b*; and then, having determined how many teeth fhall be comprehended between the pallets, call this number *n*. Multiply the angle *b* by *n* + 1, and take the half of the product. Set off this half in the circumference of the wheel (at the points of the teeth) on each fide of the line joining the centres of the crutch and wheel, as at TB and TC. Through S and *s* draw SB and *s* C, and through B draw β B *b* perpendicular to SB, for the medium pofition of the face of the firft pallet; that is, for its pofition when the pendulum hangs perpendicular. In like manner, drawing *o* C *n* perpendicular to *s* C, we have the medium pofition of the fecond pallet. The demonftration of this conftruction is very evident from what has been faid.

We have hitherto fuppofed that the pendulum finifhes its vibration at the inftant that a tooth of the wheel efcapes from a pallet, and another tooth drops on the other pallet. But this is never, or fhould never be, the cafe. The pendulum is made to fwing fomewhat beyond the angle of fcapement: for if it do not when the clock is clean and in good order, but ftop precifely at the drop of a tooth, then, when it grows foul, and the vibration diminifhes, the teeth will not efcape at all, and the clock will immediately ftop. Therefore the force communicated by the wheels during the vibration within the limits of fcapement, muft be increafed fo as to make the pendulum *throw* (as the artifts term it) farther out; and a clock is more valued when it throws out confiderably beyond the angle of fcapement. There are good reafons for this The momentum of the pendulum, and its power to regulate the clock (which Mr Harrifon fignificantly called its *dominion*), is proportional to the width of its vibrations very nearly.

This circumftance of exceeding the angle of fcapement has a very great influence on the performance of the clock, or greatly affects the dominion of the pendulum. It is eafy to fee that, when the face β *b* of the leading pallet is a plane if the pendulum continue its motion to the right, from P toward Q, after the tooth B has dropped on it, the pallet will pufh the wheel back again, while the tooth flides outward on the pallet toward β. Such pallets therefore will make a *recoiling fcapement*, refembling, in this circumftance, the old pallet employed with the crown wheel, and will have the properties attached to this circumftance. One confequence of this is, that it is much affected by any inequalities of the maintaining power. It is a matter of the moft familiar obfervation, that a common watch goes flower when within a quarter of an hour of being down, when the action of the fpring is very weak, in confequence of its not pulling by a radius of the fufee. We obferve the fame thing in the beating of an alarum clock. Alfo if we at any time prefs forward the wheelwork of a common watch with the key, we obferve its beats accelerate immediately. The reafon of this is pretty plain. The balance, in confequence of the acceleration in the angle of fcapement, would have gone much farther, employing a confiderable time in the excurfion. This is checked abruptly, which both fhortens the vibration and the time employed in it. In the return of the pendulum, the motion is accelerated the whole way, along an arch which is fhorter than what correfponds to its velocity in the middle point; for it is again checked on the other fide, and does not make its full excurfion. Moreover, all this irregularity of force, or the great deviation from a refiftance to the excurfion proportional to the diftance from the middle point, is exerted on the pendulum when it is near the end of the excurfion, where the velocity being fmall, this irregular force acts long upon it, at the very time that it has little force wherewith to refift it. All temporary inequalities of force, therefore, will be more felt in this fituation of the balance than if they had been exerted in the middle of its motion. And although the regulating power of a pendulum greatly exceeds that of the light balances ufed in pocket watches, fomething of the fame kind may be expected even in pendulum clocks. Accordingly this appears by a feries of experiments made by Mr Berthoud, a celebrated watchmaker of Paris. A clock, with a half fecond pendulum weighing five drams, was furnifhed with a recoiling fcapement, whofe pallets were planes. The angle of fcapement was $5\frac{1}{2}$ degrees. When actuated with a weight of two pounds, it fwung 8°, and loft 15″ per hour; with four pounds, it fwung 10°, and loft 6″. Thus it appears that by doubling the maintaining power, although the vibration was increafed in confequence of the greater impulfe, the time was leffened 9″ per hour, viz. about $\frac{1}{400}$. It is plain, from what was faid when we defcribed the firft fcapement, that an increafe of maintaining power muft render the vibration more frequent. We faw, on that occafion, that, even when the gravity of the pendulum is balanced by a weight on the other end of the rod, the force of the wheels will produce a vibratory motion, and that an augmentation of this force will increafe it, or make the vibrations more rapid. The precife effect of any particular form of teeth can be learned only by computing the force on the pendulum in every pofition, and then conftructing the curve *r π* C of fig 1. The rapid increafe of the ordinates beyond thofe of the triangle ADC, forms a confiderable area DA π *o*, to compenfate the area π *o* C, and thus makes a confiderable contraction A π of the vibration, and a fenfible contraction $\frac{A\theta}{2}$ of the time.

Mr George Graham, the celebrated watchmaker in London, was alfo a good mathematician, and well qualified to confider this fubject fcientifically. He contrived a fcapement, which he hoped would leave the pendulum almoft in its natural ftate. The acting face of the pallet *a b c* (fig. 4.) is a plane. The tooth drops on *a* and efcapes from *c*, and is on the middle point *b* when the pendulum is perpendicular. Beyond *a*, the face of the pallet is an arch *a d*, whofe centre is A, the centre of the crutch. The maintaining power is made fo great as to produce a much greater vibration than the angle of active fcapement *a* A *c*. The confequence of this is that, when the tooth drops on the angle *a*, the pendulum, continuing its motion, carries the crutch along with it, and the tooth paffes on the arch *a d*, in a direction paffing through the centre of the crutch. This preffure can neither accelerate nor retard the motion

 tion

tion of the crutch and pendulum. As the pendulum was accelerated after it passed the perpendicular, by the other pallet, it will (if quite unobstructed) throw out farther than what corresponds to the velocity which it had in the middle point of its vibration; perhaps till the tooth passes from *a* to *e* on the circular arch of the pallet. But although it sustains no contrary action from the wheels during this excursion beyond the angle of scapement, it will not proceed so far, but will stop when the tooth reaches *d*; because there must be some resistance arising from the friction of the tooth along the arch *a d*, and from the clamminess of the oil employed to lubricate it: but this resistance is exceedingly minute, not amounting to $\frac{1}{8}$th of the pressure on the arch. Nay, we think that it appears from the experiments of Mr Coulomb that, in the case of such minute pressures on a surface covered with oil, there is no sensible retardation analogous to that produced by friction, and that what retardation we observe arises entirely from the clamminess of the oil. We are so imperfectly acquainted with the manner in which friction and viscidity obstruct the motions of bodies, that we cannot pronounce decisively what will be their effect in the present case. Friction does not increase much, if at all, by an increase of velocity, and appears like a fixed quantity when the pressure is given. This makes all motions which are obstructed by friction terminate abruptly. This will shorten both the length and the time of the outward excursion of the pendulum. The viscidity of the oil resists differently, and more nearly in the proportion of the velocities. The diminution of motion will not be in this proportion, because in the greater velocities it acts for a shorter time. Were this accurately the case, the resistance of viscidity would also be nearly constant, and it would operate as friction does. But it does not stop a motion abruptly, and the motions are extinguished gradually. Therefore, although viscidity must always diminish the extent of the excursion, it may so vary as not to diminish the time. We apprehend, however, that it generally does. But whatever happens in the excursion, the return will certainly be slower, and employ more time than if it had not been obstructed, because the velocity in every point is less than if perfectly free. The whole arch, consisting of a returning arch and an excursion on the other side, may be either slower or quicker, according as the compensation is complete or not, or is even overdone.

All these reflections occurred to Mr Graham; and he was persuaded that the time of the tooth's remaining on the arch *a d*, both ascending and descending, would differ very little from that of the description of the same arch by a free pendulum. The great causes of irregularity seemed to be removed, viz. the inequalities in the action of the wheels in the vicinity of the extremity of the vibration, where the pendulum having little momentum is, long in the same little space, exposed to their action. The derangement produced by any force depends on the time of its action, and therefore must be greatest when the motion is slowest. The pendulum gets its impulse in the very middle of its vibration, where its velocity is the greatest; and therefore the inequalities of the maintaining power act on it only for a short time, and make a very trifling alteration in the time of its describing the arch of scapement. Beyond this, it is nearly in the state of a free pendulum; nay, even though it be affected by an inequality of the maintaining power, and it be accelerated beyond its usual rate in that arch, the chief effect of this will be to cause it to describe a larger arch of excursion. The shortening of the time of this description by the friction will be the same as before, happening at the very end of the excursion; but the return will be more retarded by the friction on a longer arch. And, by this, a compensation may be made for the trifling contraction of the time of describing the arch of scapement.

This circumstance of giving the impulse in the middle of the vibration, where its time of action is the smallest possible, and whereby the pendulum is so long left free from the action of the wheels, is of the very first importance in all scapements, and should ever be in the mind of the mechanician. When this is adhered to, the form of the face *a b c* is scarcely of any moment. Much has been written on this form, and many attempts have been made to make it such that the action of the wheels shall be proportional to the action of gravity. To do this is absolutely impossible. Mr Graham made them planes, not only because of easiest execution, but because a plane really conspires pretty well with the change of gravity. While the pendulum moves from Q to P (fig. 3.), the force of gravity, acting in the direction QP, is continually diminishing. So is the accelerating power of the pallet from *a* to *b*. When the pendulum rises from P to R, a force in the opposite direction RP continually increases. This is analogous to the continual diminution of a force in the direction PR. Now we have such a diminution of such a force, in the action of the pallet from *b* to *c*, and such an augmentation in the action of the other pallet.

For all these reasons, this construction of a scapement appeared very promising. Mr Graham put it in practice, and it answered his most sanguine expectation, and is now universally adopted in all nice clocks. Mr Graham, however, did not think it prudent to cause a tooth to drop on the very angle *a* of the pallet. He made it drop on a point *f* of the arch of excursion. This has also the advantage of diminishing the angle of action, which we have proved to be of service. It requires, indeed, a greater maintaining power; but this can easily be procured, and is less affected by the changes to which it is liable by the effect of heat and cold on the oil. Our observations on the effects of friction and viscidity in the arch *a d* seem to be confirmed by the observations of several artists, who agree in saying that a great increase of maintaining power increases the vibrations, but makes them perceptibly slower. When they wrote, much oil was applied to diminish the friction on the arch of repose; but, since that time, the rubbing parts were made such as required no oil, and this retardation disappeared. In the clock of the transit room of the Royal Observatory, the angle of action seldom exceeds one-third of the swing of the pendulum. The pallets are of oriental ruby, and the wheel is of steel tempered to the utmost degree of hardness. This clock never varies a whole second from equable motion in the course of five days.

This contrivance is known by the name of the DEAD BEAT, the DEAD SCAPEMENT; because the seconds index stands still after each drop, whereas the index of a clock with a recoiling scapement is always in motion, hobbling backward and forward.

These ſcapements, both recoiling and dead beat, have been made in a thouſand forms; but any perſon tolerably acquainted with mechanics, will ſee that they are all on the ſame principles, and differ only in ſhape or ſome equally unimportant circumſtance. Perhaps the moſt convenient of any is that repreſented in fig. 5. where the ſhaded part is the crutch, made of braſs or iron, and A and B are two pieces of agate, flint, or other hard ſtone, cut into the proper ſhape for a pallet of either kind, and firmly fixed in proper ſockets. They project half an inch, or thereabouts, in front of the crutch, ſo that the ſwing wheel is alſo before the crutch, diſtant about $\frac{1}{10}$th of an inch or ſo. Pallets of ruby, driven by a hard ſteel ſwing wheel, need no oil, but merely to be once rubbed clean with an oily cloth.

Sometimes the wheel has pins inſtead of teeth. They are ranged round the rim of the wheel, perpendicular to its plane, and both pallets are on one ſide of the wheel, ſtanding perpendicular to its plane. One of theſe pins drops from the firſt to the ſecond pallet at once. The pallets are placed on two arms, as in fig. 6. in which caſe the pins are alternately on different ſides of the wheel; or on one, as in fig. 7. By the motion of the pendulum to the right, the pin (in fig. 7.), after reſting on the concave arch *d a*, acts on the face *a c*, and drops from *c* on the other concave arch *i g*, which continues to move a little way to the right. It then returns, and the pin ſlides and acts on the pallet *i b*, and eſcapes at *b*; and the next pin is then on the arch of repoſe *d a*.

It being evident that the recoiling ſcapement accelerates the vibrations beyond the rate of a free pendulum, and it alſo appearing to many of the firſt artiſts that the dead ſcapement retards them, they have attempted to form a ſcapement which ſhall avoid both of theſe defects, by forming the arches *a d*, *i g*, ſo as to produce a very ſmall recoil. Mr Berthoud does this in a very ſimple manner, by placing the centre of *a d* at a ſmall diſtance from that of the crutch, ſo as to make the riſe of the pallet above the concentric arch about one-third of the arch itſelf. Applying ſuch a crutch to the light pendulum mentioned in a former paragraph, he found that doubling, and even trebling the maintaining power, produced no change in the time of vibration, though it increaſed the width from 8° to 12° and 14°. We have no doubt of the efficacy of this contrivance, and think it very proper for all clocks which require much oil, ſuch as turret clocks, &c. But we apprehend that no rule can be given for the angle that the recoiling arch ſhould make with the concentric one. We imagine that this depends entirely on the ſhare which friction and oil have in producing the retardation of the dead beat.

Other artiſts have endeavoured to avoid the inconveniences of friction and oil on the arch of repoſe in another way. Inſtead of allowing the tooth of the wheel to drop on the back of the pallet, which we called the *arch of excurſion*, and others call the *arch of repoſe*, it drops on a detent *o t a* (fig. 8.), of which the part *t a* is part of an arch whoſe centre is A, the centre of the crutch, and the part *t o* is in the direction of the radius. This piece does not adhere to the pallet, but is on the end of an arm *o* A, which turns round the axis A of the crutch on fine pivots: it is made to apply itſelf to the back of the pallet by means of a ſlender ſpring A *p*, attached to the pallet, and preſſing inward on a pin *p*, fixed in the arm of the detent. When ſo applied, its arch *t a* makes the repoſe, and its point *a* makes a ſmall portion of the face *a c* of the pallet.

Watch-work.

The action of this apparatus is very eaſily underſtood. When a tooth eſcapes from the ſecond pallet, by the motion of the pendulum from the left to the right, another tooth drops on this pallet (which the figure ſhews to be the firſt or leading pallet) at the angle *t*, and reſts on the ſmall portion *t a* of an arch of repoſe. But the crutch, continuing its motion to the right, immediately quits the arm *o* A, carrying the pallet *a c r* along with it, and leaving the wheel locked on the detent *o t a*. By and bye the pendulum finiſhes its excurſion to the right, and returns. When it enters the arch of action, the pallet has applied itſelf to the detent *o t a*, and withdraws it from the tooth. The tooth immediately acts on the face *a c* of the pallet, and reſtores the motion loſt during the laſt vibration. The uſe of the ſpring is merely to keep the detent applied to the pallet without ſhaking. It is a little bent during their ſeparation, and adds ſomething of an oppoſing force to the aſcent of the pendulum on the other ſide of the wheel, and accelerates its return. A ſimilar detent on the back of the ſecond pallet performs a ſimilar office, ſupporting the wheel while the pendulum is beyond the arch of ſcapement, and quitting it when the pendulum enters that arch.

We do not know who firſt practiſed this very ingenious and promiſing invention. Mr Mudge certainly did ſo early as 1753 or 1754. Mr Berthoud ſpeaks obſcurely of contrivances of the ſame nature. So does Le Roy, and (we think) Le Paute. We ſay that it is very promiſing. Friction is almoſt annihilated by transferring it to the pivots at A; ſo that, in the excurſion beyond the angle of ſcapement, the pendulum ſeems almoſt free. Indeed ſome artiſts of our acquaintance have even avoided the friction of the pivots at A, by making the arm of the detent a ſpring of conſiderable thickneſs, except very near to A, where it is made very thin and broad. But we do not find that this conſtruction, though eaſily executed, and ſuſceptible of great preciſion and ſteadineſs of action, is much practiſed. We preſume that the performance has not anſwered expectations. It has not been ſuperior to the incomparably more ſimple dead ſcapement of Graham. Indeed we think that it cannot. A part of the friction ſtill remains, which cannot be removed; namely, while the arch *t a* is drawn from between the tooth and pallet. Nay, we apprehend that ſomething more than friction muſt be overcome here. The tooth is apt to force the detent outward, unleſs the part *t a* be a little elevated at its point *a* like a claw, above the concentric arch, and the face of the tooth be made to incline forward, ſo as to fit this ſhape of the detent. This will conſume ſome force, when the momentum of the pendulum is by no means at its maximum. Should the clock be foul, and the excurſions beyond ſcapement be very ſmall, this diſturbance muſt be exceedingly pernicious. But we have a much greater objection. During the whole excurſion beyond ſcapement, there is a new force of a ſpring acting on the pendulum, which deviates conſiderably from the proportions of the accelerating power of gravity. It does not commence its action till the detent ſeparates from the arm of the crutch. Then the ſpring of the detent acts as a retarding force

against

against the excursion of the pendulum, now on the other side, bringing it sooner to rest, and then accelerating it in its way back to the beginning of the arch of scapement. In short, this construction should have the properties of a recoiling scapement. We got a clock-maker to make some experiments on one which he had made for an amateur, which fully confirmed our conjecture. When the detent spring was strong, an increase of maintaining power made the vibrations both wider and more rapid. The artist reduced the strength of the spring till this effect was rendered very small. It might perhaps be quite removed by means of a still weaker spring: But the spring was already so weak that a hard step on the floor of the room did sometimes disengage the detent from the wheel. It appears, therefore, that nothing can be reasonably expected from this construction that is not as well performed by the dead scapement of Mr Graham, of much easier execution, and more certain performance.

Very similar to this construction (at least in the excursion beyond the angle of scapement) is the construction of Mr Cumming, and it has the same defects. His pallets are carried, as in the one described, by the crutch. The detents press on them behind by their weight only: therefore, when the tooth is locked on the detent of one pallet, its weight is taken off from the pendulum on that side, and the weight of the detent on the other side opposes the ascent, and accelerates the descent of the pendulum.

Mr Cumming executed another scapement, consisting, like those, of a pallet and detent. But the manner of applying the maintaining power is extremely different in principle from any yet described. It is exceedingly ingenious, and seems to do all that is possible for removing every source of irregularity in the maintaining power, and every obstruction to free motion arising from friction and oil in the scapement. For this reason we shall give such an account of its essential circumstances as may suffice to give a clear conception of its manner of acting, and its good properties and defects; but referring the inquisitive reader to Mr Cumming's Elements of Clock and Watch Work, published in 1766, for a more full account.

In the scapements last described, the pallets were fixed to the crutch and pendulum, and the maintaining power, during its action, was applied to the pendulum by means of the pallets, in the same way as in ordinary scapements. The detents were unconnected with the pendulum. and it was free during the whole excursion. In the present scapement both the pallets and detents are detached from the pendulum, except in the moment of unlocking the wheel; so that the pendulum may be said to be free during its whole vibration, except during this short moment.

ABC (fig. 9.) represents a portion of the swing wheel, of which O is the centre, and A one of the teeth; Z is the centre of the crutch, pallets, and pendulum. The crutch or detents is represented of a form resembling the letter A, having in the circular cross piece a slit *i k*, also circular, Z being the centre. This form is very different from Mr Cumming's, and inferior to his, but was adopted here in order to avoid a long description. The arm ZF forms the first detent, and the tooth A is represented as locked on it at F. D is the first pallet on the end of the arm Z *d* moveable round the same centre with the detents, but moveable independently of them. The arm *d c*, to which the pallet D is attached, lies altogether behind the arm ZF of the detent, being fixed to a round piece of brass *e f g*, which has pivots turning concentric with the verge or axis of the pendulum. To the same round piece of brass is fixed the horizontal arm *e* H. carrying at its extremity the ball H, of such size, that the action of the tooth A on the pallet D is just able (but without any risk of failing) to raise it up to the position here drawn. ZP*p* represents the fork, or the pendulum rod, behind both detent and pallet. A pin *p* projects forward, coming through the slit *i k*, without touching the upper or under margin of it. There is also attached to the fork the arm *m n* (and a similar one on the other side), of such length that, when the pendulum rod is perpendicular, as is represented here, the angular distance of *n q* from the rod *e q* H is precisely equal to the angular distance of the left side of the pin *p* from the left end *i* of the slit *i k*.

The mode of action on this apparatus is abundantly simple. The natural position of the pallet D is at *s*, represented by the dotted lines, resting on the back of the detent F. It is naturally brought into this position by its own weight, and still more by the weight of the ball H. The pallet D, being set on the fore side of the arm at Z, comes into the same plane with the detent F and the swing-wheel. It is drawn, however, in the figure in another position. The tooth C of the wheel is supposed to have escaped from the second pallet, on which the tooth A immediately engages with the pallet D, situated at *s*, forces it out, and then rests on the detent F, the pallet D leaning on the tip of the tooth. F is brought into this situation in a way that will appear presently. After the escape of C, the pendulum, moving down the arch of semivibration, is represented as having attained the vertical position. Proceeding still to the left, the pin *p* reaches the extremity *i* of the slit *i k*; and, at the same instant, the arm *n* touches the rod *e* H in *q*. The pendulum proceeding a hair's breadth further, withdraws the detent F from the tooth, which now even pushes off the detent, by acting on the slant face of it. The wheel being now unlocked, the tooth following C on the other side acts on its pallet, pushes it off, and rests on its detent, which has been rapidly brought into a proper position by the action of A on the slant face of F. It was a similar action of C on its detent, in the moment of escape, which brought F into a fit position for locking the wheel by the tooth A. The pendulum still going on, the arm *m n* carries the weight of the ball H, and the pallet connected with it, and it comes to rest before the pin *p* again reaches the end of the slit, which had been suddenly withdrawn from it by the action of A on the slant face of F. The pendulum now returns towards the right, loaded on the left with the ball H, which restores the motion which it had lost during the last vibration. When, by its motion to the right, the pin *p* reaches the end *k* of the slit *i k*, it unlocks the wheel on the right side. At the same instant the weight H ceases to act on the pendulum, being now raised up from it by the action of a tooth like B on the pallet D.

Let us now consider the mechanism of these motions. The prominent feature of the contrivance is the almost complete disengagement of the regulator from the wheels.

The wheels, indeed, act on the pallets; but the pallets are then detached from the pendulum. The ſole uſe of the wheel is to raiſe the little weights while the pendulum is on the other ſide, in order to have them in readineſs at the arrival of the pendulum. They are then laid on the pendulum, and ſupply an accelerating force, which reſtores to the pendulum the momentum loſt during the preceding vibration. Therefore no inequalities in the action of the wheel on the pallets, whether ariſing from friction or oil, has any effect on the maintaining power. It remains always the ſame, namely, the rotative momentum of the two weights. The only circumſtance, in which the irregularity of the action of the wheels can affect the pendulum is at the moment of unlocking. Here indeed the regulator may be affected; but this moment is ſo ſhort, in compariſon with other ſcapements, that it muſt be conſidered as a real improvement.

It is very uncandid to refuſe the author a claim to the character of an ingenious artiſt on account of this contrivance, as has been done by a very ingenious univerſity Profeſſor, who taxes Mr Cumming with ignorance of the *firſt elements of mechanics*, and ſays that the beſt thing in his book is his advice to ſuſpend the pendulum from a great block of marble, firmly fixed in the wall *. This is certainly a good advice, and we doubt not but that the Profeſſor's clock would have performed ſtill better if he had condeſcended to follow it. It is ſtill leſs candid to queſtion the originality of the invention. We know for certain that it was invented at a time and place where the author *could* not know what had been done by others. It would have been more like the urbanity of a well educated man to have acknowledged the genius, which, without ſimilar advantages, had done ſo much.

* See *Ludlam's Eſſay*.

But, while we thus pay the tribute of juſtice to Mr Cumming, we do not adopt all his opinions. The clock has the ſame defects of the former in reſpect of the laws of the force which accelerates the pendulum. The ſudden addition of the ſmall weight, and this almoſt at the extremity of the vibration, would derange it very much, if the addition were ſuſceptible of any ſenſible variation. The irregularity of the action of the wheels *may* ſenſibly affect the motion during the unlocking, when the clock is foul, and the pendulum *juſt* able to unlock; for any diſturbance at the extremity of the vibration greatly affects the time. We acknowledge that the parts which we here ſuppoſe to be foul may not be ſo in the courſe of twenty years, theſe parts being only the pivots of the ſcapement. The great defect of the ſcapement is its liableneſs to unlock by any jolt. It is more ſubject to this than the others already mentioned. This riſk is much increaſed by the ſlender make of the parts, in Mr Cumming's drawings, and in the only clock of the kind we have ſeen; but this is not neceſſary; and it ſhould be avoided for another reaſon; the interpoſing ſo many ſlender and crooked parts between the moving power and the pendulum weakens the communication of power, and requires a much more powerful wheelwork.

All theſe, however, are ſlight defects, and only the laſt can be called a fault. The clocks made on this principle have gone remarkably well, as may be ſeen by the regiſters of his majeſty's private obſervatory. But the greateſt objection is, that they do not perform better than a well-made dead ſcapement; and they are vaſtly more troubleſome to make and to manage. This is ſtrictly true, and is a ſerious objection. The fact is, that the dominion of a heavy pendulum is ſo great, that if *any one* of the ſcapements now deſcribed be well executed with pallets of agate, and a wheel of hard ſteel, and if the pendulum be ſuſpended agreeably to Mr Cumming's advice, there is hardly any difference to be obſerved in their performance. We ſhall content ourſelves with a ſingle proof of this from fact. The clock invented by the celebrated Harriſon is *at leaſt equal* in its performance to any other. Friction is almoſt annihilated, and no oil is required. It went fourteen years without being touched, and during that time did not vary one complete ſecond from one day to another, nor ever deviated half a minute by accumulation from equable motion: Yet the ſcapement, in ſo far as it reſpects the law of the accelerating force, deviates more from the proportion of the ſpaces than the moſt recoiling ſcapement that ever was put to a good clock. It is ſo different from all hitherto deſcribed, both in form and principle, that we muſt not omit ſome account of it, and with it we ſhall conclude our ſcapements for clocks.

Let GDO repreſent the ſwing-wheel, of which M is the centre. A is the verge or axis of the pendulum. It has two very ſhort arms AB, AE. A ſlender rod BC turns on fine pivots in the joint B, and has at its extremity C a hook or claw, which takes hold of a tooth D of the ſwing-wheel when the pendulum moves from the right ſide to the left. This claw, when at liberty, ſtands at right angles, or, at leaſt, in a certain determinate angle, with regard to the arm AB; and when drawn a little from that poſition, it is brought back to it again by a very ſlender ſpring. The arm AE is furniſhed with a detent EF, which alſo, when at liberty, maintains its poſition on the arm by means of a very ſlender ſpring.

Let us now ſuppoſe that the tooth D is preſſing on the claw C, while the pendulum is moving to the right. The joint B yields, by its motion round A, to the preſſure of the tooth on the claw. By this yielding, the angle ABC opens a little. In the mean time, the ſame motion round A cauſes the point F of the detent on the other ſide to approach the circumference of the wheel in the arch of a circle, and the tooth G at the ſame time advances. They meet, and the point of G is lodged in the notch under the projecting heel *f*. When this takes place, it is evident that any farther motion of the point E round A muſt puſh the tooth G a little backward, by means of the detent EF. It cannot come any nearer to the wheel, becauſe the point of the tooth ſtops the heel *f*. The inſtant that F puſhes G back, the tooth D is withdrawn from the claw C, and C flies out, by the action of its ſpring, and reſumes its poſition at right angles to BA; and the wheel is now free from the claw, but is puſhing at the detent F (c). The pendulum, having

(c) The reader may here remark the manner in which the preſſure of the tooth G on the detent is transferred to the joint E by the intervention of the ſhank FE, and from the joint E to the pendulum rod, by the intervention

ving finiſhed its excurſion to the right (in which it cauſes the wheel to recoil by means of the detent F), returns toward the left. The wheel now advances again, and, by preſſing on F, aids the pendulum through the whole angle of ſcapement. By this motion the claw C deſcribes an arch of a circle round A, and approaches the wheel, till it take hold of another tooth, namely, the one following D, and pulls it back a little. This immediately frees the detent F from the preſſure of the tooth G, and it flies out a little from the wheel, reſuming its natural poſition by means of its ſpring. Soon after, the motion of the pendulum to the left ceaſes, and the pendulum returns; D pulling forward the hook C to aid the pendulum, and the former operation is repeated, &c. &c.

Such is the operation of the pallets of Harriſon and Hindley. Friction is almoſt totally avoided, and oil entirely (D). The motion is given to the pendulum by a fair pull or puſh, and the teeth of the wheel only apply themſelves to the detents without rubbing. There is no drop, and the ſcapement makes no noiſe, and is what the artiſts call *a ſilent ſcapement*. The mechanician will readily perceive, that by properly diſpoſing the arms AB, AE, and diſpoſing the pallets on the circumference of the wheel, the law, by which the action of the wheel on the pendulum is regulated, may be greatly varied, ſo as to harmonize, as far as the nature of ſcapement, alternately puſhing and pulling, will admit, with the action of gravity.

But this is evidently a recoiling ſcapement, and one of the worſt kind; for the recoil is made at the very confines of the vibration, where every diſturbance of the regular cycloidal vibration occaſions the greateſt diſturbance to the motion. Yet this clock kept time with moſt unexampled preciſion, far excelling all that had been made before, and equal to any that have been made ſince. This is entirely owing to the immenſe ſuperiority of the momentum of the pendulum over the maintaining power.

II. *Of Scapements for a Watch.*

THE execution of a proper ſcapement for watches is a far more delicate and difficult problem than the foregoing, on account of the ſmall ſize, which requires much more accurate workmanſhip, becauſe the error of the hundredth part of an inch has as great a proportion to the dimenſions of the regulator as an inch in a common houſe clock. It is much more difficult on another account. We have no ſuch means of accumulating ſuch a dominion (to uſe Mr Harriſon's expreſſive term) over the wheel-work in the regulator of a watch as in that of a clock. The heavieſt balance that we can employ, without the certainty of ſnapping its pivots by every ſlight jolt, is a mere trifle, in compariſon with the pendulum of the moſt ordinary clock. A dozen or twenty grains is the utmoſt weight of the balance, even of a very large pocket watch. The only way that we can accumulate any notable quantity of regulating power in ſuch a ſmall pittance of matter is by giving it a very great velocity. This we do by accumulating all its weight in the rim, by giving it very wide vibrations, and by making them extremely frequent. The balance-rim of a middling good watch ſhould paſs through at leaſt ten inches in every ſecond. Now, when we reflect on the ſmall momentum of this regulator, the inevitable inequalities of the maintaining power, and the great arch of vibration on which theſe inequalities will operate, and the comparative magnitude even of an almoſt inſenſible friction or clamminеſs, it appears almoſt chimerical to expect any thing near to equability in the vibrations, and incredible that a watch can be made which will not vary more than one beat in 86400. Yet ſuch have been made. They muſt be conſidered as the moſt maſterly exertions of human art. The performance of a reflecting teleſcope is a great wonder: the worſt that can find a market muſt have its mirrors executed without an error of the ten thouſandth part of an inch; but we now know that this accuracy is attained almoſt in ſpite of us, and that we ſcarcely *can* make them of a worſe figure. But the caſe is far otherwiſe in watch work. Here all thoſe wonderful approaches to perfection are the reſults of rational diſcuſſion, by means of ſound principles of ſcience; and, unleſs the artiſt who puts theſe principles into practice be more than a mere copyiſt, unleſs the principles themſelves are perceived by him, and actually direct his hand, the watch may ſtill be good for nothing. Surely, then, this is a liberal art, and far above a manual knack. The ſtudy of the means by which ſuch wonders are ſteadily effected, is therefore the ſtudy of a gentleman.

In the account given above of the ſcapements for pendulums, we aſſumed as one leading principle that *the natural vibrations of a pendulum are performed in equal times, whether wide or narrow.* This is ſo nearly true, when the arches on each ſide of the perpendicular do not exceed four degrees, that the retardation of the wider arches within that limit will not become ſenſible, though accumulated for a long time. The common ſcapement with a plane face of the pallet, helps to correct even this ſmall inequality much better than the niceſt form of the cycloidal cheeks propoſed by Huyghens.

In watch-work we aſſume a ſimilar principle, namely, that *the oſcillations of a balance, urged by its ſpring, and undiſturbed*

tion of the arm EA. This communication of preſſure is preciſely the ſame that we made uſe of in explaining the common ſcapement. MG, FE, and EA, in this fig. 10. are performing the offices which we then gave to the lines MB, BH, and HA, in fig. 3. Harriſon's pallet realiſes the abſtract theory.

(D) Mr Harriſon was at firſt by profeſſion a carpenter in a country place. Being extremely ingenious and inventive, he had made a variety of curious wooden clocks. He made one, in particular, for a turret in a gentleman's houſe. Its expoſure made it waſte oil very faſt, and the maker was often obliged to walk two or three miles to renew it, and got nothing for his trouble. In trudging home, not in very good humour, he pondered with himſelf how to make a clock go without oil. He changed all his pinion leaves into rollers; which anſwered very well. But the pallets required it more than any other part. After various other projects, he contrived thoſe now repreſented, where there was no friction, and no oil is wanted. The turret clock continued to go without being touched till Mr Harriſon left the country.

Watch-work.

undisturbed by all foreign forces are performed in equal times, whether they be wide or narrow. This principle was assumed by the celebrated mechanician Dr Robert Hooke, on the authority of many experiments which he had made on the bending and unbending of springs. He found that the force necessary for retaining a spring in any constrained position was proportional to its tension, or deflection from its natural form. He expressed this in an anagram, which he published about the year 1660, in order to establish his claim to the discovery, and yet conceal it, till he had made some important application of it. When the anagram was explained some years afterwards, it was, "*Ut tensio, sic vis.*" Dr Hooke thought of applying this discovery to the regulation of watch movements. For, if a slender spring be *properly* applied to the axis of a watch balance, it will put that balance in a certain determinate position. If the balance be turned aside from this position, it seems to follow that it will be urged back toward it by a force proportional to its distance from it. He immediately made the application to an old watch, which he afterward gave to Dr Wilkins, Bishop of Chester. This was in 1658. Its motion was so amazingly improved, that Hooke was persuaded of the perfection of his principle, and thought that nothing was now wanting for making a watch of this kind a perfect chronometer but the hand of a good workman. For his watch seemed almost perfect, though made in a small country town, in a very coarse manner. Mr Huyghens also claims this discovery. He published his claim about the year 1675, and proposed to make watches for discovering the longitude of a ship at sea. But there is the most unquestionable evidence of Dr Hooke's priority by fifteen years, and of his having made several watches of this kind. One of them was in the possession of his majesty king Charles II. Dr Hooke's first balance spring was straight, and acted on the balance in a very imperfect manner. But he soon saw the imperfections, and made several successive alterations; and, among others, he employed the cylindrical spiral now employed by Mr Arnold; but he gave it up for the flat spiral: and the king's watch had one of this kind before Mr Huyghens published his invention. His project of longitude watches had been carried on along with Lord Brouncker and Sir Robert Moray, and they had quarrelled some years before that publication. See WATCH, *Encycl.*

But both Dr Hooke and Mr Huyghens were too sanguine in their expectations. We, by no means, have the evidence for the truth of this principle that we have for the accelerating action of gravity on a pendulum. It rests on the nicety and the propriety of the experiments; and long experience has shewn that it is sensibly true only within certain limits. The demonstrations by which Bernoulli supports the unqualified principle of Mr Huyghens, proceed on hypothetical doctrines concerning the nature of elasticity. And even these shew that the law of elasticity which he assumed was selected, not because founded on simpler principles than any other, but because it was consistent with the experiments of Hooke and Huyghens. Besides, although this should be the true law of a spring, it does not follow that this spring, applied in *any way* to the axis of a balance, will urge that balance agreeably to the same law: and if it did, it still does not follow that the oscillations of the balance will be isochronous; for the spring has to move not only the balance but also the spring. Part of the restoring force of the spring is employed in restoring it rapidly to its quiescent shape, and thus enabling it to *follow and still impel* the yielding balance. It is therefore only the surplus which is employed in actually moving the balance, and it is uncertain whether this surplus varies according to the same law, being always the same proportion of the whole force of the spring. We find it an extremely difficult problem to determine the law of variation of this surplus, even in the simplest form of the spring; nay, it is by no means an easy problem to determine the law of oscillation of a spring, unloaded with any balance; and we can easily shew that there are such forms of a spring, that although the velocity with which the different parts approach to their quiescent position be exactly as their excursion from it, this is by no means the law of velocity which this spring will produce in a balance. The matter of fact is, that when the spring is a simple straight steel wire, suspending the balance in the direction of its axis, the motions of it, if not immoderate, are precisely agreeable to Huyghens's and Hooke's rule; and that the motion of a balance urged by a spring wound up into a flat, or a cylindrical spiral, as in common watches, and those of Arnold, deviates sensibly from it, unless a certain analogy be preserved between the length and the elasticity of the spring. If the spring be immoderately long, the wide vibrations are slower than the narrow ones; and the contrary is observed when the spring is immoderately short. A certain taper, or gradual diminution of the spring, is also found to have an effect in equalizing the wide and narrow vibrations. There is also a great difference between the force with which a part of the spring unbends itself, and the action of that force in urging the balance round its axis; and the performance of many watches, good in other respects, is often faulty from the manner in which this unbending force is employed.

But, since these corrections are in our power in a considerable degree, we may suppose them applied, and the true motion (which we shall call the cycloidal) attained; and we may then adapt the construction of the scapement to the preserving this motion undisturbed. And here we must see at once that the problem is incomparably more delicate than in the case of pendulums. The vibrations must be very wide, and the angular motion rapid, that it may be little affected by external motions. The smallest inequalities of maintaining power acting through so great a space, must bear a considerable proportion to the very minute momentum of a watch balance. Oil is as clammy on the pallets of a watch as on those of a clock; a viscidity which would never be felt by a pendulum of 20 pounds weight will stop a balance of 20 grains altogether. For the same reason, it is evident that any impropriety in the form of the pallet must be incomparably more pernicious than in the case of a pendulum; the deviation which this may occasion from a force proportional to the angular distance from the middle point, must bear a great proportion to the whole force.

The common recoiling scapement of the old clocks still holds its place in the ordinary pocket watches, and answers all the common purposes of a watch very well. A well finished watch, with a recoiling scapement, will

will keep time within a minute in the day. This is enough for the ordinary affairs of life. But such watches are subject to great variation in their rate of going, by any change in the power of the wheels. This is evident; for if the watch be held back, or pressed forward, by the key applied to the fusee square, we hear the beating greatly retarded or accelerated. The maintaining power, in the best of such watches, is never less than one-fifth of the regulating power of the spring. For, if we take off the balance spring, and allow the balance to vibrate by the impulse of the wheels alone, we shall find the minute hand to go forward from 25 to 30 minutes per hour. Suppose it 30. Then, since the wheels act through equal spaces with or without a spring, the forces are as the squares of the acquired velocities. (DYNAMICS, *Suppl.* n° 95) The velocity in this case is double; therefore the accelerating force is quadruple, and the force of the spring is three times that of the wheels. If the hand goes forward 25 minutes, the force of the wheels is about one-fifth of that of the spring. This great proportion is necessary, as already observed, that the watch may go as soon as unstopped.

We have but little to say on this scapement; its principle and manner of action, and its good and bad qualities, being the same with those of the similar scapement for pendulums. It is evident that the maintaining power being applied in the most direct manner, and during the whole of the vibration, it will have the greatest possible influence to move the balance. A given mainspring and train will keep in motion a heavier balance by means of this scapement than by any other. But, on the other hand, and for the same reason, the balance has less dominion over the wheel-work, and its vibrations are more affected by any irregularities of the wheel-work. Moreover, the chief action of the wheel being at the very extremities of the vibrations, and being very abrupt, the variations in its force are most hurtful to the isochronism of the vibrations.

Although this scapement is extremely simple, it is susceptible of more degrees of goodness or imperfection than almost any other, by the variation of the few particulars of its construction. We shall therefore briefly describe that construction which long experience has sanctioned as approaching near to the best performance that can be obtained from the common scapement. Fig. 11. represents it in what are thought its best proportions, as it appears when looking straight down on the end of the balance arbor. C is the centre of the balance and verge. CA and CB are the two pallets; CA being the upper pallet, or the one next to the balance, and CB being the lower one. F and D are two teeth of the crown wheel, moving from left to right; and E, G, are two teeth on the lower part of the circumference, moving from right to left. The tooth D is represented as just escaped from the point of CA, and the lower tooth E as just come in contact with the lower pallet. The scapement should not, however, be quite so close, because an inequality on the teeth might prevent D from escaping at all. For if E touch the pallet CB before D has quitted CA, all will stand still. This fault will be corrected by withdrawing the wheel a little from the verge, or by shortening the pallets.

The proportions are as follow. The distance between the front of the teeth (that is, of G, F, E, D) and the axis C of the balance is one-fifth of FA, the distance between the points of the teeth. The length CA, CB of the pallets is three-fifths of the same distance. The pallets make an angle ACB of 95 degrees, and the front DH or FK of the teeth make an angle of 25° with the axis of the crown-wheel. The sloping side of the tooth must be of an epicycloidal form, suited to the relative motion of the tooth and pallet.

From these proportions it appears that the pallet A can *throw out*, by the action of the tooth D, till it reaches *a*, 120 degrees from CL, the line of the crown-wheel axis For it can throw out till the pallet B strike against the front of E, which is inclined 25° to CL. To this add BCA, = 95°, and we have LC*a* = 120. In like manner B will throw out as far on the other side. From 240°, the sum of these angles, take the angle of the pallets 95°, and there remains 145° for the greatest vibration which the balance can make without striking the front of the teeth. This extent of vibration supposes the teeth to terminate in points, and the acting surfaces of the pallets to be planes directed to the very axis of the verge. But the points of the teeth must be rounded off a little for strength, and to diminish friction on the face of the pallets. This diminishes the angle of scapement very considerably, by shortening the teeth. Moreover, we must by no means allow the point of the pallet to bank or strike on the foreside of a tooth. This would greatly derange the vibration by the violence and abruptness of the check which the wheel would give to the pallet. This circumstance makes it improper to continue the vibrations much beyond the angle of scapement. One-third of a circle, or 120°, is therefore reckoned a very proper vibration for a scapement made in these proportions. The impulse of the wheels, or the angle of scapement, may be increased by making the face of the pallets a little concave (preserving the same angle at the centre). The vibration may also be widened by pushing the wheel nearer to the verge. This would also diminish the recoil. Indeed this may be entirely removed by bringing the front of the wheel up to C, and making the face of the pallet not a radius, but parallel to a radius and behind it, *i. e.* by placing the pallet CA so that its acting face may be where its back is just now. In this case, the tooth D would drop on it at the centre, and lie there at rest, while the balance completes its vibration. But this would make the banking (as the stroke is called) on the teeth almost unavoidable. In short, after varying every circumstance in every possible manner, the best makers have settled on a scapement very nearly such as we have described. Precise rules can scarcely be given; because the law by which the force acting on the pallets varies in its intensity, deviates so widely from the action of the balance spring, especially near the limits of the excursions."

The discoveries of Huyghens and Newton in rational mechanics engaged all the mathematical philosophers of Europe in the solution of mechanical problems, about the end of the last century. The vibrations of elastic plates or wires, and their influence on watch balances, became familiar to every body. The great requisites for producing isochronous vibrations were well understood; and the artists were prompted by the speculatists to attempt constructions of scapements proper for this purpose. It appeared clearly, that the most effectual means for

Watch-work.

for this purpose was to leave the balance unconnected with the wheels, especially near the extremities of the vibration, where the motion is languid, and where every inequality of maintaining power must act for a longer time, and therefore have a great effect on the whole duration of the vibrations. The maxim of construction that naturally arises from these reflections is to *confine*, if possible, *the action of the wheels to the middle of the vibration*, where the motion is rapid, and where the chief effect of an increase or diminution of the maintaining power will be to enlarge or contract the angular motions, but will make little change on their duration; because the greatest part of the motion will be effected by the balance spring alone. This maxim was inculcated in express terms by John Bernoulli, in his *Recherches Mechaniques et Physiques*; but it had been suggested by common sense to several unlettered artists before that time. About the beginning of this century watches were made in London, where the verge had a portion *e d b* (fig. 12.) of a small cylinder, having its centre *c* in the axis, and a radial pallet *b a* proceeding from it. Suppose a tooth just escaped from the point of the pallet, moving in the direction *b d e*, the cylindrical part was so situated that the next tooth dropped on it at a small distance from its termination. While the verge continues turning in the direction *b d e*, the tooth continues resting on the cylinder, and the balance sustains no *action* from the wheels, and has only to overcome the minute frictions on the polished surface of a hard steel cylinder. This motion may perhaps continue till the pallet acquires the position *f*, almost touching the tooth. It then stops, its motion being extinguished by the increasing force of the spring. It now returns, moving in the direction *e d b*; and when the pallet has acquired the position *c i*, the tooth *g* quits the circumference of the cylinder, and drops in on the pallet at the very centre. The crooked form of the tooth allows the pallet to proceed still farther, before there is any danger of banking on the tooth. This vibration being also ended, the balance resumes its first direction, and the tooth now acts on the face of the pallet, and restores to the balance all the motion which it had lost by friction, &c. during the two preceding vibrations.

It is evident that this construction obviates all the objections to the former recoiling scapement, and that, by sufficiently diminishing the diameter of the cylindrical part, the friction may be reduced to a very small quantity, and the balance be made to move by the action of the spring during the whole of the excursion, and of the returning vibration. Yet this construction does not seem to have come much into use, owing, in all probability, to the great difficulty of making the drop so accurate in all the teeth. The smallest inequality in the length of a tooth would occasion it to drop sooner or later; and if the cylinder was made very small, to diminish friction, the formation of the notch was almost a microscopical operation, and the smallest shake in the axis of the verge or the balance-wheel would make the tooth slip past the cylinder, and the watch run down amain.

About the same time, a French artist in London (then the school of this art) formed another scapement, with the same views. We have not any distinct account of it, but are only informed (in the 7th volume of the *Machines approuvées par l'Acad. des Sciences*) that the tooth rested on the surface of a hollow cylinder, and then escaped by acting on the inclined edge of it. But we may presume that it had merit, being there told that Sir Isaac Newton wore a watch of this kind.

A much superior scapement, on the same principle, was invented by Mr Geo. Graham, at the same time that he changed the recoiling scapement for pendulums into the dead beat. Indeed it is the same scapement, accommodated to the large vibrations of a balance. In fig. 13. DE represents part of the rim of the balance-wheel. A and C are two of its teeth, having their faces *b e* formed into planes, inclined to the circumference of the wheel, in an angle of about 15 degrees; so that the length *b e* of the face is nearly quadruple of its height *e m*. Suppose a circular arch ABC described round the centre of the wheel, and through the middle of the faces of the teeth. The axis of the balance passes thro' some point B of this arch, and we may say that the mean circumference of the teeth passes through the centre of the verge. On this axis is fixed a portion of a thin hollow cylinder *b c d*, made of hard tempered steel, or of some hard and tough stone, such as ruby or sapphire. Agates, though very hard, are brittle. Chalcedony and cornelian are tough, but inferior in hardness. This cylinder is so placed on the verge, that when the balance is in its quiescent position, the two edges *b* and *d* are in the circumference which passes through the points of the teeth. By this construction the portion of the cylinder will occupy 210° of the circumference, or 30° more than a semicircle. The edge *b*, to which the tooth approaches from without, is rounded off on both angles. The other edge *d* is formed into a plane, inclined to the radius about 30°.

Now, suppose the wheel pressed forward in the direction AC. The point *b* of the tooth, touching the rounded edge, will push it outwards, turning the balance round in the direction *b c d*. The heel *e* of the tooth will escape from this edge when it is in the position *h*, and *e* is in the position *f*. The point *b* of the tooth is now at *d*, but the edge of the cylinder has now got to *i*. The tooth, therefore, rests on the inside of the cylinder, while the balance continues its vibration a little way, in consequence of the shove which it has received from the action of the inclined plane pushing it out of the way, as the mould board of a plough shoves a stone aside. When this vibration is ended, by the opposition of the balance-spring, the balance returns, the tooth (now in the position B) rubbing all the while on the inside of the cylinder. The balance comes back into its natural position *b c d*, with an accelerated motion, by the action of its spring, and would, of itself, vibrate as far, at least, on the other side. But it is aided again by the tooth, which, pressing on the edge *d*, pushes it aside, till it come into the position *k*, when the tooth escapes from the cylinder altogether. At this moment the other edge of the cylinder is in the position *l*, and therefore is in the way of the next tooth, now in the position A. The balance continues its vibration, the tooth all the while resting, and rubbing on the outside of the cylinder. When this vibration, in the direction *d c b*, is finished, the balance resumes its first motion *bcd*, by the action of the spring, and the tooth begins to act on the first edge *b*, as soon as the balance gets into its natural position, shoves it aside, escapes from it, and drops on the inside of the cylinder. In this manner are

the

the vibrations produced, gradually increased to their maximum, and maintained in that state. Every succeeding tooth of the wheel acts first on the edge b, and then on the edge d; resting first on the outside, and then on the inside of the cylinder. The balance is under the influence of the wheels while the edge b passes to h, and while d passes to k; and the rest of the vibration is performed without any *action* on the part of the wheels, but is a little obstructed by friction, and by the clamminess of the oil. In the construction now described, the arch of action or scapement is evidently 30°, being twice the angle which the face of a tooth makes with the circumference.

The reader will perceive, that when this scapement is executed in such a manner that the succeeding tooth in contact with the cylinder at the instant that the preceding one escapes from it, the face of the tooth must be equal to the inside diameter of the cylinder, and that the distance between the heel of one tooth and the point of the following one must be equal to the outside diameter. When the scapement is so close there is no drop. A good artist approaches as near to this adjustment as possible; because, while a tooth is dropping, but not yet in contact, it is not acting on the balance, and some force is lost. The execution is accounted very good, if the distance between the centres of two teeth is twice the external diameter of the cylinder. This allows a drop equal to the thickness of the cylinder, which is about $\frac{1}{10}$th of its diameter.

We must also explain how this cylinder is so connected with the verge as to make such a great revolution round the tooth of the wheel. The triangular tooth $e\,b\,m$ is placed on the top of a little pillar or pin fixed into the extremity of the piece of brass m D formed on the rim of the wheel. Thus the wedge-tooth has its plane parallel to the plane of the wheel, but at a small distance above it. Fig. B represents the verge, a long hollow cylinder of hard steel. A great portion of the metal is cut out. If it were spread out flat, it would have the shape of fig. C. Suppose this rolled up till the edges GH and G′H′ are joined, and we have the exact form. The part acted on by the point of the tooth is the dotted line $b\,d$. The part DIFE′ serves to connect the two ends. Thus it appears to be a very slender and delicate piece; but being of tempered steel, it is strong enough to resist moderate jolts. The ruby cylinders are much more delicate.

Such is the cylinder scapement of Mr Graham, called also the HORIZONTAL SCAPEMENT, because the balance wheel is parallel to the others. Let us see how far it may be expected to answer the intended purposes. If the excursions of the balance beyond the angle of impulsion were made altogether unconnected with the wheels, the *whole vibration* would be quicker than one of the same extent, made by the action of the balance-spring alone, because the middle part of it is accelerated by the wheels. But the excursions are obstructed by friction and the clamminess of oil. The effect of this in *obstructing* the motion is very considerable. Mr Le Roy placed the balance so, that it rested when the point of the tooth was on the middle of the cylindric surface. When the wheel was allowed to press on it, and it was drawn 80° from this position, it vibrated only during 4½ seconds. When the wheel was not allowed to touch the cylinder, it vibrated 90 seconds, or 20 times as long; so much did the friction on the cylinder exceed that of the pivots. We are not sufficiently acquainted with the laws of either of these obstructions to pronounce decidedly whether they will increase or diminish the *time* of the whole vibrations. We observe distinctly, in motions with considerable friction, that it does not increase nearly so fast as the velocity of the motion; nay, it is often less when the velocity is very great. In all cases it is observed to terminate motions abruptly. The friction requires a certain force to overcome it, and if the body has any less it will stop. Now this will not only contract the excursion of the balance, but will shorten the time. But the return to the angle of impulsion will undoubtedly be of longer duration than the excursion; for the arch of return, from the extremity of the excursion to its beginning, where the angle of impulsion ends, is the same with the arch of excursion. The velocity which the balance has in any point of the return is less than what it had in the same point of the excursion; because, in the excursion, it had velocity enough to carry it to the extremity, and also to overcome the friction. In the return, it could, even without friction, only have the velocity which would have carried it to the extremity; and this smaller velocity is diminished by friction during the return. The velocity being less through the whole return than during the excursion, the time must be greater. It may therefore happen that this retardation of the return may compensate the contraction of the excursion and the diminution of its duration. In this case the vibration will occupy the same time as if the balance had been free from the wheels. But it may more than compensate, and the vibrations will then be slower; or it may not fully compensate, and they will be quicker. We cannot therefore say, *à priori*, which of the two will happen: but we may venture to say that an increase of the force of the wheels will make the watch go slower: for this will exert a greater pressure, give a greater impulsion, produce a wider excursion, and increase the friction during that greater excursion, making the wide vibrations slower than the narrow ones; because the angle of impulsion remaining the same, the pressures exerted must be quadrupled, in order to double the excursion (see DYNAMICS, n° 95. *Suppl.*), and therefore the friction will be increased in a greater proportion than the momentum which is to overcome it. But, with respect to the obstruction arising from the viscidity of the oil, we know that it follows a very different law. It bears a manifest relation to the velocity, and is nearly proportional to it. But still it is difficult to say how this will affect the whole vibration. The duration of the excursion will not be so much contracted as by an equal obstruction from friction, because it will not terminate the motion abruptly. There are therefore more chances of the increased duration of the return exceeding the diminution of it in the excursion. All that we can say, therefore, is, that there will be a compensation in both cases. The time of excursion will be contracted, and that of return augmented.

Now, as the friction may be greatly diminished by fine polish, fine oil, and a small diameter of the cylinder, we may reasonably expect that the vibrations of such a balance will not vary nearly so much from isochronism as with a recoiling scapement, and will be little affected by changes in the force of the wheels.

Watch-work.

Accord-

Accordingly, Graham's cylindrical ſcapement ſupplanted all others as ſoon as it was generally known. We cannot compare the vibrations with thoſe of a free balance, becauſe we have no way of making a free balance vibrate for ſome hours. But we find that doubling or trebling the force of the wheels makes very little alteration in the rate of the watch, though it greatly enlarges the angular motion. Any one may perceive the immenſe ſuperiority of this ſcapement over the common recoiling ſcapement, by preſſing forward the movement of a horizontal watch with the key, or by keeping it back. No great change can be obſerved in the frequency of the beats, however hard we preſs. But a more careful examination ſhews that an increaſe of the power of the wheels generally cauſes the watch to go ſlower; and that this is more remarkable as the watch has been long going without being cleaned. This ſhews that the cauſe is to be aſcribed to the friction and oil operating on the wide arches of excurſion. But when this ſcapement is well executed, in the beſt proportions of the parts, the performance is extremely good. We know ſuch watches, which have continued for ſeveral weeks without ever varying more than 7″ in one day from equable motion. We have ſeen one whoſe cylinder was not concentric with the balance, but ſo placed on the verge that the axis of the verge was at o (fig. 13.), between the centre B of the cylinder and the entering edge b, and Bc was equal to the thickneſs of the cylinder. The watch was made by Emery of London, and was ſaid to go with aſtoniſhing regularity, ſo as to equal any time-piece while the temperature of the air did not vary; and when clean, was ſaid to be leſs affected by the temperature than a watch with a free ſcapement, but unprovided with a compenſation piece. It is evident that this watch muſt have a minute recoil. This was ſaid to be the aim of the artiſt, in order to compenſate for the obſtruction cauſed by friction during the return of the balance from its excurſions. It indeed promiſes to have this effect; but we ſhould fear that it ſubjects the excurſions to the influence of the wheels. We ſuſpect that the indifferent performance of cylinder watches may often ariſe from the cylinder being off the centre in ſome diſadvantageous manner.

The watch from which the proportions here ſtated were taken, is a very fine one made by Graham for Archibald Duke of Argyle, which has kept time with the regularity now mentioned. We believe that there are but few watches which have ſo large a portion of the cylinder: few indeed have more than one half, or 180° of the circumference. But this is too little. The tooth of the wheel does not begin to act on the reſting cylinder till its middle point A or B touch one of the edges. To obtain the ſame angle of ſcapement, the inclination of the face of the tooth muſt be increaſed (it muſt be doubled); and this requires the maintaining power to be increaſed in the ſame proportion. Beſides, in ſuch a ſcapement it may happen that the tooth will never reſt on the cylinder; becauſe the inſtant that it quits one edge it falls on the other, and puſhes it aſide, ſo that the balance acquires no wider vibration than the angle of ſcapement, and is continually under the influence of the wheels. The ſcapement is in its beſt ſtate when the portion of the cylinder exceeds 180° by twice the inclination of the teeth to the circumference of the wheel.

It would employ volumes to deſcribe all the ſcapements which have been contrived by different artiſts, aiming at the ſame points which Graham had in view. We ſhall only take notice of ſuch as have ſome eſſential difference in principle.

Fig. 14. repreſents a ſcapement invented in France, and called the *Echappement à Virgule*, becauſe the pallet reſembles a comma. The teeth A, B, C, of the balance wheel are ſet very oblique to the radius, and there is formed on the point of each a pin, ſtanding up perpendicular to the plane of the wheel. This greatly reſembles the wheel of Graham's ſcapement, when the triangular wedge is cut off from the top of the pin on which it ſtands. The axis c of the verge is placed in the circumference paſſing through the pins. The pallet is a plate of hard ſteel $a\,e\,f\,d\,b$, having its plane parallel to the plane of the wheel. The inner edge of this plate is formed into a concave cylindrical ſurface between o and b, whoſe axis c coincides with the axis of the verge. Adjoining to this is the acting face $b\,d$ of the pallet. This is either a ſtraight line $b\,d$, making an angle of nearly 30° with a line $c\,b\,g$ drawn from the centre, or it is more generally curved, according to the noſtrum of the artiſt. The back of the pallet $a\,e\,f$ is alſo a cylindrical ſurface (convex) concentric with the other. This extends about 100° from a to f. The part between f and d may have any ſhape. The interval $a\,o$ is formed into a convex ſurface, in ſuch a manner as to be everywhere interſected by the radius in an angle of 30° nearly; *i. e.* it is a portion of an equiangular ſpiral. The whole of this is connected with the verge by a crank, which paſſes perpendicularly through it between f and e; and the plate is ſet at ſuch height on the crank or verge, that it can turn round clear of the wheel, but not clear of the pins. The teeth of the wheel are ſet ſo obliquely, and made ſo ſlender, that the verge may turn almoſt quite round without the crank's banking on the teeth. The part $f\,d\,b$, called the horn, is of ſuch a length, that when one pin B reſts on the outſide cylinder at a, the point d is juſt clear of the next pin A.

When the wheel is not acting, and the balance ſpring is in equilibrio, the poſition of the balance is ſuch that the point d of the horn is near i, about 30° from d. The figure repreſents it in the poſition which it has when the tooth A has juſt eſcaped from the point d of the horn. In this poſition the next tooth B is applied to the convex cylinder, a very little way (about 5°) from its extremity a. This deſcription will enable the reader to underſtand the operation of the virgule ſcapement.

Now ſuppoſe the pin A juſt eſcaped from the horn. The ſucceeding pin B is now in contact with the back of the cylinder; and the balance, having got an impulſe by the action of A along the concave pallet $b\,d$, continues its motion in the direction $d\,g\,h$, till its force is ſpent, the point of the horn arriving perhaps at h, more than 90° from d. All this while the following tooth B is reſting on the back $e\,f$ of the cylinder. The balance now returns, by the action of its ſpring; and when the horn is at i, the pin gets over the edge $a\,o$, and drops on the oppoſite ſide of the concave cylinder, where it reſts, while the horn moves from i to k, where it ſtops, the force of the balance being again ſpent. The balance then returns; and when the horn comes within

30° of *d*, the pin gets out of the hollow cylinder, shoves the horn out of its way, and escapes at *d*. Besides the impulse which the balance receives by the action of the wheel on the horn *b d*, there is another, though smaller, action in the contrary direction, while the point of B passes over the surface *a o*; for this surface being inclined to the radius, the pressure on it urges the balance round in the direction *b d i*.

The chief difference of this scapement from the former is that the inclined plane is taken from the teeth of the wheel, and placed on the verge. This alone is a considerable improvement; for it is difficult to shape all the teeth alike; whereas the horn *b d* is invariable. Moreover, the resting parts, although they be drawn large in this figure for the sake of distinctness, may be made vastly smaller than Graham's cylinder, which must be big enough to hold a tooth within it. By this change, the friction, during the repose of the wheel, that is, during the excursions of the balance, may be vastly diminished. The inside cylinder need be no bigger than to receive the pin. But although the performance of these scapements is excellent, they have not come into general use in this country. The cause seems to be the great nicety requisite in making the pins of the wheel pass exactly through the axis of the verge. The least shake in the pivots of the balance and balance-wheel must greatly change the action. A very minute increase of distance between the pivots will cause the pin B to slide from the edge *a* to the horn, without resting at all on the inside cylinder; and when it does so, it will stop the balance at once, and, immediately after, the watch will run down. The same irregularities will happen if all the pins be not at precisely the same distance from the axis of the wheel.

This scapement was greatly improved, and, in appearance, totally changed, by Mr Lepaute of Paris in 1753. By placing the pins alternately on the two sides of the rim of the balance-wheel, he avoided the use of the outside cylinder altogether. The scapement is of such a singular form, that it is not easy to represent it by any drawing. We shall endeavour, however, to describe it in such a manner as that our readers, who are not artists, will understand its manner of acting. Artists by profession will easily comprehend how the parts may be united which we represent as separate.

Let ABC (fig. 15.) represent part of the rim of the balance-wheel, having the pins 1, 2, 3, 4, 5, &c. projecting from its faces; the pins 1, 3, 5, being on the side next the eye, but the pins 2 and 4 on the farther side. D is the centre of the balance and verge, and the small circle round D represents its thickness. But the verge in this place is crooked, like a crank, that the rim of the wheel may not be interrupted by it. This will be more particularly described by and bye. There is attached to it a piece of hard tempered steel *a b c d*, of which the part *a b c* is a concave arch of a circle, having D for its centre. It wants about 30° of a semicircle. The rest of it *c d* is also an arch of a circle, having the same radius with the balance-wheel. The natural position of the balance is such, that a line drawn from D, through the middle of the face *c d*, is a tangent to the circumference of the wheel. But, suppose the balance turned round till the point *d* of the horn comes to *d'*, and the point *c* comes to 2, in the circumference in which the pins are placed. Then the pin, pressing on the beginning of the horn or pallet, pushes it aside, slides along it, and escapes at *d*, after having generated a certain velocity in the balance. So far this scapement is like the virgule scapement described already. But now let another pallet, similar to the one now described, be placed on the other side of the wheel, but in a contrary position, with the acting face of the pallet turned away from the centre of the wheel. Let it be so placed at E, that the moment that the pin 1, on the upper side of the wheel, escapes from the pallet *c d*, the pin 4, on the under side of the wheel, falls on the end of the circular arch *e f g* of the other pallet. Let the two pallets be connected by means of equal pulleys G and F on the axis of each, and a thread round both, so that they shall turn one way. The balance on the axis D, having gotten an impulse from the action of the pin 1, will continue its motion from A towards *i*, and will carry the other pallet with a similar motion round the centre E from *b* towards *k*. The pin 4 will therefore rest on the concave arch *g f e* as the pallet turns round. When the force of the balance is spent, the pallet *c d* returns towards its first position. The pallet *g b* turns along with it; and when the point of the first has arrived at *d*, the beginning *g* of the other arrives at the pin 4; and, proceeding a little farther, this pin escapes from the concave arch *e f g*, and slides along the pallet *g b*, pushing it aside, and therefore urging the pallet round the centre E, and consequently (by means of the connection of the pulleys) urging the balance on the axis D round at the same time, and in the same direction. The pin 4 escapes from the pallet *g b*, when *b* arrives at 3; but in the time that the pin 4 was sliding along the yielding pallet *g b*, the pin 3 is moving in the circumference BDA; and the instant that the pin 4 escapes from *b* at 3, the pin 3 arrives at 2, and finds the beginning *c* of the concave arch *c b a* ready to receive it. It therefore rests on this arch, while the balance continues its motion. This perhaps continues till the point *b* of the arch comes to 2. The balance now stops, its force being spent, and then returns; and the pin 3 escapes from the circle at *c*, slides along the yielding pallet *c d*, and when it escapes at 1, another pin on the under side of the wheel arrives at 4, and finds the arch *g f e* ready to receive it. And in this manner will the vibration of the balance be continued.

This description of the mode of action at the same time points out the dimensions which must be given to the parts of the pallet. The length of the pallet *c d* or *g b* must be equal to the interval between two succeeding pins, and the distance of the centres D and E must be double of this. The radius D *e* or E *g* may be as small as we please. The concave arches *c b a* and *g f e* must be continued far enough to keep a pin resting on them during the whole excursion of the balance. The angle of scapement, in which the balance is under the influence of the wheels, is had by drawing D *c* and D *d*. This angle *c* D *d* is about 30°, but may be made greater or less.

Fig. B will give some notion how the two pallets may be combined on one verge. KL represents the verge with a pivot at each end. It is bent into a crank MNO, to admit the balance wheel between its branches. BC represents this wheel, seen edgewise, with its pins, alternately on different sides. The pallets are also represented

Watch-work.

preſented edgewiſe by $b\,c\,d$ and $b\,g\,f$, fixed to the inſide of the branches of the crank, fronting each other. The poſition of their acting faces may be ſeen in the preceding figure, on the verge D, where the pallet $g\,b$ is repreſented by the dotted line $2\,i$, as being ſituated behind the pallet $c\,d$. The remote pallet $2\,i$ is placed ſo, that when the point d of the near pallet is juſt quitted by a pin 1 on the upper ſide of the wheel, the angle formed by the face and the arch of reſt of the other pallet is juſt ready to receive the next pin 2, which lies on the under ſide of the rim. A little attention will make it plain, that the action will be preciſely the ſame as when the pallets were on ſeparate axes. The pin 1 eſcapes from d, and the pin 2 is received on the arch of reſt, and locks the wheel while the balance is continuing its motion. When it returns, 2 gets off the arch of reſt, puſhes aſide the pallet $2\,i$, eſcapes from it when i gets to 1, and then the pin 3 finds the point c ready to receive it, &c. The vibrations may be increaſed by giving a ſufficient impulſe through the angle of ſcapement. But they cannot be more than a certain quantity, otherwiſe the top N of the crank will ſtrike the rim of the wheel. By placing the pins at the very edge of the wheel, the vibrations may eaſily be increaſed to a ſemicircle. By placing them at the points of long teeth, the crank may get in between them, and the vibrations extended ſtill farther, perhaps to 240°.

This ſcapement is unqueſtionably a very good one; and when equally well executed, ſhould excel Graham's, both by having but two acting faces to form (and theſe of hard ſteel or of ſtone), and by allowing us to make the circle of reſt exceedingly ſmall without diminiſhing the acting face of the pallet. This will greatly diminiſh the friction and the influence of oil. But, on the other hand, we apprehend that it is of very difficult execution. The figure of the pallets, in a manner that ſhall be ſuſceptible of adjuſtment and removal for repair, and yet ſufficiently accurate and ſteady, ſeems to us a very delicate job.

Mr Cumming, in his Elements of Clock and Watch-work, deſcribes (ſlightly) pallets of the very ſame conſtruction, making what he conceives to be conſiderable improvements in the form of the acting faces and the curves of reſt. He has alſo made ſome watches with this ſcapement; but they were ſo difficult, that few workmen can be found fit for the taſk; and they are exceedingly delicate, and apt to be put out of order. The connection of the pallets with each other, and with the verge, makes the whole ſuch a contorted figure, that it is eaſily bent and twiſted by any jolt or unſkilful handling.

There remains another ſcapement of this kind, having the tooth of the balance-wheel reſting on a cylindrical ſurface on the axis of the verge during the excurſions of the balance beyond the angle of ſcapement, and which differs ſomewhat in the application of the maintaining power from all thoſe already deſcribed.

This is known by the name of *Dupleix's ſcapement*, and is as follows: Fig 16. repreſents the eſſential parts greatly magnified. AD is a portion of the balance-wheel, having teeth f, b, g, at the circumference. Theſe teeth are entirely for producing the *reſt* of the wheel, while the balance is making excurſions beyond the ſcapement. This is effected by means of an agate cylinder $o\,p\,q$, on the verge. This cylinder has a notch o. When the cylinder turns round in the direction $o\,p\,q$, the notch eaſily paſſes the tooth B which is reſting on the cylindric ſurface; but when it returns in the direction $q\,p\,o$, the tooth B gets into the notch, and follows it, preſſing on one ſide of it till the notch comes into the poſition o. The tooth, being then in the poſition b, eſcapes from the notch, and another tooth drops on the convex ſurface of the cylinder at B.

The balance-wheel is alſo furniſhed with a ſet of ſtout flat-ſided pins, ſtanding upright on its rim, as repreſented by a, D. There is alſo fixed on the verge a larger cylinder GFC above the ſmaller one $o\,p\,q$, with its under ſurface clear of the wheel, and having a pallet C, of ruby or ſapphire, firmly indented into it, and projecting ſo far as juſt to keep clear of the pins on the wheel. The poſition of this cylinder, with reſpect to the ſmaller one below it, is ſuch that, when the tooth b is eſcaped from the notch, the pallet C has juſt paſſed the pin a, which was at A while B reſted on the ſmall cylinder; but it moved from A to a, while B moved to b. The wheel being now at liberty, the pin a exerts its preſſure on the pallet C in the moſt direct and advantageous manner, and gives it a ſtrong impulſion, following and accelerating it till another tooth ſtops on the little cylinder. The angle of ſcapement depends partly on the projection of the pallet, and partly on the diameter of the ſmall cylinder and the advance of the tooth B into the notch. Independent of the action on the ſmall cylinder, the angle of ſcapement would be the whole arch of the large cylinder between C and x. But a ſtops before it is clear of the pallet, and the arch of impulſion is ſhortened by all the ſpace that is deſcribed by the pin while a tooth moves from B to b. It ſtops at a'.

We are informed by the beſt artiſts, that this ſcapement gives great ſatisfaction, and equals, if it do not excel, Graham's cylindrical ſcapement. It is eaſier made, and requires very little oil on the ſmall cylinder, and none at all on the pallet. They ſay that it is the beſt for pocket watches, and is coming every day more into repute. Theory ſeems to accord with this character. The reſting cylinder may be made very ſmall, and the direct impulſe on the pallet gives it a great ſuperiority over all thoſe already deſcribed, where the action on the pallet is oblique, and therefore much force is loſt by the influence of oil. But we fear that much force is loſt by the tooth B ſhifting its place, and thus ſhortening the arch of impulſion; for we cannot reckon much on the action of B on the ſide of the notch, becauſe the lever is ſo extremely ſhort. Accordingly, all the watches which we have ſeen of this kind have a very ſtrong main ſpring in proportion to the ſize and vibration of the balance. If we leſſen this diminution of the angle of impulſion, by leſſening the cylinder $o\,p\,q$, and by not allowing B to penetrate far into the notch, the ſmalleſt inequality of the teeth, or ſhake in the pivots of the balance or wheel, will cauſe irregularity, and even uncertainties in the locking and unlocking the wheel by this cylinder.

A ſcapement exceedingly like this was applied long ago by Dutertre, a French artiſt, to a pendulum. The only difference is, that in the pendulum ſcapement the ſmall cylinder is cut through to the centre, half of it only being left; but the pendulum ſcapement gives a more effective employment of the maintaining power, becauſe the

Watch-work.

the wheel acts on the pallet during the *whole* of the assisted vibration. In a balance scapement, if we attempt to diminish the inefficient motion of the pin from A to *a*, by lessening the diameter of the small cylinder, the hold given to the tooth in the notch will be so trifling, that the tooth will be thrown out by the smallest play in the pivot holes, or inequality in the length of the teeth.

With this we conclude our account of scapements, where the action of the maintaining power on the balance is suspended during the excursion beyond the angle of impulsion, by making a tooth rest on the surface of a small concentric cylinder. In such scapements, the balance, during its excursions, is almost free from any connection with the wheels, and its isochronism is disturbed by nothing but the friction on this surface.—We come now to scapements of more artful construction, in which the balance is really and completely free during the whole of its excursion, being altogether disengaged from the wheelwork. These are called DETACHED SCAPEMENTS. They are of more recent date. We believe that Mr Le Roi was the first inventor of them, about the year 1748. In the Memoirs of the Academy of Paris for that year, and in the Collection of approved Machines and Inventions, we have descriptions of the contrivance. The balance-wheel rests on a detent, while the balance *is* vibrating in perfect freedom. It has a pallet standing out from the centre, which, in the course of vibration, passes close by the point of a tooth of the wheel. At that instant a pin, connected with this pallet, withdraws the detent from the wheel, and the tooth just now mentioned follows the pallet with rapidity, and gives it a smart push forward. Immediately after, another tooth of the wheel meets the other claw of the detent, and the wheel is again locked. When the balance returns, the pin pushes the detent back into its former place, where it again locks the wheel. Then the balance, resuming its first direction, unlocks the wheel, and receives another impulsion from it. Thus the balance is unconnected with the wheels, except while it gets the impulsion, and at the moments of unlocking the wheels.

This contrivance has been reduced to the greatest possible simplicity by the British artists, and seems scarcely capable of farther improvement. The following is one of the most approved constructions. In fig. 17. *a b c* represents the pallet, which is a cylinder of hard steel or stone, having a notch *a b*. A portion of the balance-wheel is represented by AB. It is placed so near to the cylinder that the cylinder is no more than clear of *two adjoining* teeth. DE is a long spring, so fixed to the watch-plate at E, as to press very gently on the stop pin G. A small stud F is fixed to that side of the spring that is next to the wheel. The tooth of the wheel rests on this stud, in such a manner that the tooth *a* is just about to touch the cylinder, and the tooth *f* is just clear of it. Another spring, extremely slender, is attached to the spring DE, on the side next the balance wheel, and claps close to it, but keeping clear of the stud F, and having its point *o* projecting about $\frac{1}{15}$th of an inch beyond its extremity. When the point *o* is pressed towards the wheel, it yields most readily; but, when pressed in the opposite direction, it carries the spring DE along with it. The cylinder being so placed on the verge that the edge *a* of the notch is close by the tooth *a*, a hole is drilled at *i*, close by the projecting point of the slender spring, and a small pin is driven into this hole. This is the whole apparatus; and this situation of the parts corresponds to the quiescent position of the balance.

Now, let the balance be turned out of this position 80 or 90 degrees, in the direction *a b c*. When it is let go, it returns to this position with an accelerated motion. The pin *i* strikes on the projecting point of the slender spring, and, pressing the strong spring DE outward from the wheel, withdraws the stud F from the tooth; and thus unlocks the wheel. The tooth *a* engages in the notch, and urges round the balance. The pin *i* quits the slender spring before the tooth quits the notch; so that when it is clear of the pallet, the wheel is locked again on the stud F, and another tooth *g* is now in the place of *a*, ready to act in the same manner. When the force of the balance is spent, it stops, and then returns toward its quiescent position with a motion continually accelerated. The pin *i* arrives at the point *o* of the slender spring, raises it from the strong spring without disturbing the latter, and almost without *being* disturbed by this trifling obstacle; and it goes on, turning in the direction *a b c*, till its force is again spent; it stops, returns, again unlocks the wheel, and gets a new impulsion. And in this manner the vibrations are continued. Thus we see a vibration, almost free, maintained in a manner even more simple than the common crutch scapement. The impulse is given direct, without any decomposition by oblique action, and it is continued through the *whole* motion of the wheel. No part of this motion is lost, as in Dupleix's scapement, by the *gradual* approach of the tooth to its active position. Very little force is required for unlocking the wheel, because the spring DFE is made slender at the remote end E, so that it turns round E almost like a lever turning on pivots. A sudden twitch of the watch, in the direction *b a*, might chance to unlock the wheel. But this will only derange one vibration, and even that not considerably, because the teeth are so close to the cylinder that the wheel cannot advance till the notch comes round to the place of scapement. A tooth will continue pressing on the cylinder, and by its friction will change a little the extent and duration of a single vibration. The greatest derangement will happen if the wheel should thus unlock by a jolt, while the notch passes through the arch of scapement in the returning vibration. Even this will not greatly derange it, when the watch is clean and vibrating wide; because, in this position, the balance has its greatest momentum, and the direction of the only jolt that can unlock the wheel tends to increase this momentum relatively. In short, considering it theoretically, it seems an almost perfect scapement; and the performance of many of these watches abundantly confirms that opinion. They are known to keep time for many days together, without varying one second from day to day; and this even under considerable variations of the maintaining power. Other detached scapements may equal this, but we scarcely expect any to exceed it; and its simplicity is so much superior to any that we have seen, that, on this account, we are disposed to give it the preference. We do not mean to say that it is the best for a pocket watch. Perhaps the scapement of Dupleix or Graham may be preferable, as being susceptible

ceptible of greater ftrength, and more able to withftand jolts. Yet it is a fact that fome of the watches made in this form by Arnold and others have kept time in the wonderful manner abovementioned while carried about in the pocket.

Mr Mudge of London invented, about the year 1763, another detached fcapement, of a ftill more ingenious conftruction. It is a counterpart of Mr Cumming's fcapement for pendulums. The contrivance is to this effect. In fig. 18. *a b c* reprefents the balance. Its axis is bent into a large crank EFGHIK, fufficiently roomy to admit within it two other axes M and L, with the proper cocks for receiving their pivots. The three axes form one ftraight line. About thefe fmaller axes are coiled two auxiliary fprings, in oppofite directions, having their outer extremities fixed in the ftuds A and B The balance has its fpring alfo, as ufual, and the three fprings are fo difpofed that each of them alone would keep the balance at reft in the fame pofition, which we may fuppofe to be that reprefented in the figure. The auxiliary fprings A and B are connected with the balance only occafionally, by means of the arms *m* and *n* projecting from their refpective axes. Thefe arms are catched on oppofite fides by the pins *o*, *p*, in the branches of the crank; fo that when the balance turns round, it carries one or other of thofe arms round with it, and, during this motion, it is affected by the auxiliary fpring connected with the arm fo carried round by it.

Let us fuppofe that the balance vibrates 120° on each fide of its quiefcent pofition *a b c*, fo that the radius E *a* acquires, alternately, the pofitions E *b* and E *c*. The auxiliary fprings are connected with the wheels by a common dead-beat pendulum fcapement, fo that each can be feparately wound up about 30°, and retained in that pofition. Let us alfo fuppofe that the fpring A has been wound up 30° in the direction *a b*, by the wheel-work, and that the point *a* of the rim of the balance, having come from *c*, is paffing through *a* with its greateft velocity. When the radius E *a* has paffed *a* 30° in its courfe toward *b*, the pin *o* finds the arm *m* in its way, and carries it along with it till *a* gets to *b*. But, by carrying away the arm *m*, it has unlocked the wheel-work, and the fpring B is now wound up 30° in the other direction, but has no connection with the balance during this operation. Thus the balance finifhes its femivibration *a b* of 120°, oppofed by its own fpring the whole way, and by the auxiliary fpring A through an angle of 90°. It returns to the pofition E *a*, aided by A and by the balance-fpring, through an angle of 120°. In like manner, when E *a* has moved 30° toward the pofition E *c*, the pin *p* meets with the arm *n*, and carries it along with it through an angle of 90°, oppofed by the fpring B, and then returns to the pofition E *a*, affifted by the fame fpring through an arch of 120°.

Thus it appears that the balance is oppofed by each auxiliary fpring through an angle of 90°, and affifted through an angle of 120°. This difference of action maintains the vibrations, and the neceffary winding up of the auxiliary fprings is performed by the wheel-work, at a time when they are totally difengaged from the balance. No irregularity of the wheel-work can have any influence on the force of the auxiliary fprings, and therefore the balance is completely difengaged from all thefe irregularities, except in the fhort moment of unlocking the wheel that winds up the fprings.

This is a moft ingenious conftruction, and the neareft approach to a free vibration that has yet been thought of. It deferves particular remark that, during the whole of the returning or accelerated femivibration, the united force of the fprings is proportional to the diftance from the quiefcent pofition. The fame may be faid of the retarded excurfion beyond the angle of impulfe: therefore the only deviation of the forces from the law of cycloidal vibration is during the motion from the quiefcent pofition to the meeting with the auxiliary fpring. Therefore, as the forces, on both fides, beyond this angle, are in their due proportion, and the balance always makes fuch excurfions, there feems nothing to difturb the ifochronifm, whether the vibrations are wide or narrow. Accordingly, the performance of this fcapement, under the fevereft trials, equalled any that were compared with it, in as far as it depended on fcapement alone. But it is evident that the execution of this fcapement, though moft fimple in principle, muft always be vaftly more difficult than the one defcribed before. There is fo little room, that the parts muft be exceedingly fmall, requiring the moft accurate workmanfhip. We think that it may be greatly fimplified, preferving all its advantages, and that the parts may be made of more than twice their prefent fize, with even lefs load on the balance from the inertia of matter. This improvement is now carrying into effect by a friend.

Still, however, we do not fee that this fcapement is, theoretically, fuperior to the laft. The irregularities of maintaining power affect that fcapement only in the arch of impulfion, where the velocity is great, and the time of action very fmall. Moreover, the chief effect of the irregularities is only to enlarge the excurfions; and in thefe the wheels have no concern.

Mr Mudge has alfo given another detached fcapement, which he recommends for pocket watches, and executed entirely to his fatisfaction in one made for the Queen. A dead beat pendulum fcapement is interpofed, as in the laft, between the wheels and the balance. The crutch EDF (fig. 19.) has a third arm DG, ftanding outwards from the meeting of the other two, and of twice their length. This arm terminates in a fork AGB. The verge V has a pallet C, which, when all is at reft, would ftand between the points A, B of the fork. But the wheel, by its action on the pallet E, forces the fork into the pofition B *g b*, the point A of the fork being now where B was before, juft touching the cylindrical furface of the verge. The fcapement of the crutch EDF is not accurately a dead beat fcapement, but has a very fmall recoil beyond the angle of impulfion. By this circumftance the branch A (now at B) is made to prefs moft gently on the cylinder, and keeps the wheel locked, while the balance is going round in the direction BHA. The point A gets moving from A to B by means of a notch in the cylinder, which turns round at the fame time by the action of the branch AG on the pallet C; but A does not touch the cylinder during this motion, the notch leaving free room for its paffage. When the balance returns from its excurfion, the pallet C ftrikes on the branch A (ftill at B), and unlocks the wheel. This now acting [illegible] he crutch

Watch-work.

crutch pallet F, causes the branch b of the fork to follow the pallet C and give it a strong impulse in the direction in which it is then moving, causing the balance to make a semivibration in the direction AHB. The fork is now in the situation A g a, similar to B g b, and the wheel is again locked on the crutch pallet E.

The intelligent reader will admit this to be a very steady and effective scapement. The lockage of the wheel is procured in a very ingenious manner; and the friction on the cylinder, necessary for effecting this, may be made as small as we please, notwithstanding a very strong action of the wheel: For the pressure of the fork on the cylinder depends entirely on the degree of recoil that is formed on the pallets E and F. *Pressur* on the cylinder is not *indispensably* necessary, and the crutch scapement might be a real dead beat. But a small recoil, by keeping the fork in contact with the cylinder, gives the most perfect steadiness to the motion. The ingenious inventor, a man of approved integrity and judgment, declares that her Majesty's watch was the best pocket watch he had ever seen. We are not disposed to question its excellency. We saw an experiment watch of this construction, made by a country artist, having a balance so heavy as to vibrate only twice in a second. Every vibration was sensibly beyond a turn and a half, or 540°. The artist assured us, that when its proper balance was in, vibrating somewhat more than five times in a second, the vibrations even exceeded this. He had procured it this great mobility by substituting a roller with fine pivots in place of the simple pallet of Mudge. This great extent of detached vibration is an unquestionable excellence, and is peculiar to those two scapements of this ingenious artist.

Very ingenious scapements have been made by Ernshaw, Howel, Hayley, and other British artists; and many by the artists of Paris and Geneva. But we must conclude the article, having described all that have any difference in principle.

The scapement having been brought to this degree of perfection, we have an opportunity of making experiments on the law of action of springs, which has been too readily assumed. We think it easy to demonstrate, that the figure of a spring, which must have a great extent of rapid motion, will have a considerable influence on the force which it impresses on a balance *in actual motion*. The accurate determination of this influence is not very difficult in some simple cases. It is the greatest of all in the plane spiral, and the least in the cylindrical; and, in this last form, it is so much less as the diameter is less, the length of the spring being the same. By employing many turns, in order to have the same ultimate force at the extremity of the excursion, this influence is increased. A particular length of spring, therefore, will make it equal to a given quantity; and it may thus compensate for a particular magnitude of friction, and other obstructions. This accounts for the observation of Le Roy, who found that every spring, *when applied to a movement*, had a certain length, which made the wide and narrow vibrations isochronous. His method of trial was so judicious, that there can be no doubt of the justness of his conclusion. His time-keeper had no fuzee; and when the last revolution of the main wheel was going on, the vibrations were but of half the extent of those made during the first revolution. Without minding the real rate of going, he only compared the duration of the first and last revolution of the minute hand. An artist of our acquaintance repeated these experiments, and with the same result: But, unfortunately, could derive little benefit from them; because in one state of the oil, or with one balance, he found the lengths of the same spring, which produced isochronous vibrations, were different from those which had this effect in another state of the oil, or with another balance. He also observed another difference in the rate, arising from a difference of position, according as XII, VI, III, or IX, was uppermost; which difference plainly arises from the swagging of the spring by its weight, and, in that state, acting as a pendulum. This unluckily put a stop to his attempts to lessen this hurtful influence by employing a cylindrical spiral of small diameter and great length.

WATER Blowing Machine, called in French *Soufflet d'eau* or *trompe*, is a machine which, by the action of falling water, supplies air to a blast furnace. It consists of an upright pipe, through which a shower of water is made to fall; and this shower carries down with it a mass of air, which is received beneath in a kind of tub, and conducted to the furnace by means of a pipe. The first idea of such a machine was doubtless suggested by those local winds, which are always produced by natural falls of water over precipices, and in the mountains (see page 278 of this Volume); but perhaps we are indebted for the first accurate theory of it to Professor Venturi.

That philosopher, in his experimental researches concerning the lateral communication of motion in fluids, proves that the water-blowing machine affords air to the furnace, by the accelerating force of gravity and the lateral communication of motion combined together. He begins with an idea, which, he candidly acknowledges, did not escape the penetration of Leonardo Da Vinci. Suppose a number of equal balls to move in contact with each other along the horizontal line AB (Plate XLVI. fig. 1.). Imagine them to pass with an uniform motion, at the rate of four balls in a second. Let us take BF, equal to 16 feet English. During each second four balls will fall from B to F, and their respective distances in falling will be nearly BC = 1, CD, = 3, DE = 5, EF = 7. We have here a very evident representation of the separation, and successive elongation, which the accelerating force of gravity produces between bodies which fall after each other.

The rain water flows out of gutters by a continued current; but during its fall it separates into portions in the vertical direction, and strikes the pavement with distinct blows. The water likewise divides, and is scattered in the horizontal direction. The stream which issues out of the gutter may be one inch in diameter, and strike the pavement over the space of one foot. The air which exists between the vertical and horizontal separations of the water which falls, is impelled and carried downwards. Other air succeeds laterally; and in this manner a current of air or wind is produced round the place struck by the water. Hence the following idea of a water-blowing machine:

Let BCDE (fig. 2.) represent a pipe, through which the water of a canal AB falls into the lower receiver MN. The sides of the tube have openings all round, through which the air freely enters to supply what the water carries down in its fall. This mixture of water

and

and air proceeds to strike a mass of stone Q; whence rebounding through the whole width of the receiver MN, the water separates from the air, and falls to the bottom at XZ, whence it is discharged into the lower channel or drain, by one or more openings TV. The air being less heavy than the water, occupies the upper part of the receiver; whence being urged through the upper pipe O, it is conveyed to the forge.

It has been supposed by some eminent chemists, that the air which passes through the pipe O is furnished by the decomposition of water. To ascertain whether this be the case or not, our author formed a water-blowing engine of a small size. The pipe BD was two inches in diameter, and four feet in height. When the water accurately filled the section BC, and all the lateral openings of the pipe BDEC were closed, the pipe O no longer offered any wind. It is therefore evident, that in the open pipes the whole of the wind comes from the atmosphere, and no portion is afforded by the decomposition of water. It remains, therefore, to determine the circumstances proper to drive into the receiver MN the greatest quantity of air, and to measure that quantity.

1. To obtain the greatest effect from the acceleration of gravity, it is necessary that the water should begin to fall at BC, (fig. 2.) with the least possible velocity; and that the height of the water FB should be no more than is necessary to fill the section BC. Our author supposes the vertical velocity of this section to be produced by an height or head equal to BC.

2. We do not yet know, by direct experiment, the distance to which the lateral communication of motion between water and air can extend itself; but we may admit with confidence, that it can take place in a section double that of the original section with which the water enters the pipe. Let us suppose the section of the pipe BDEC to be double the section of the water at BC; and, in order that the stream of fluid may extend and divide itself through the whole double section of the pipe, some bars, or a grate, are placed in BC, to distribute and scatter the water through the whole internal part of the pipe.

3. Since the air is required to move in the pipe O with a certain velocity, it must be compressed in the receiver. This compression will be proportioned to the sum of the accelerations, which shall have been destroyed in the inferior part KD of the pipe. Taking KD $= 1{,}5$ feet, we shall have a pressure sufficient to give the requisite velocity in the pipe O. The sides of the portion KD, as well as those of the receiver MN, must be exactly closed in every part.

4. The lateral openings in the remaining part of the pipe BK may be so disposed and multiplied, particularly at the upper part, that the air may have free access within the tube. We will suppose them to be such that 0,1 foot height of water might be sufficient to give the necessary velocity to the air at its introduction through the apertures.

All these conditions being attended to, and supposing the pipe BD to be cylindrical, it is required to determine the quantity of air which passes in a given time through the circular section KL. Let us take in feet $KB = 1{,}5$; $BC = BF = a$; $BD = b$. By the common theory of falling bodies, the velocity in KL will be $7{,}76\sqrt{(a+b-1{,}4)}$; the circular section KL $= 0{,}785\,a^2$. Admitting the air in KL to have acquired the same velocity as the water, the quantity of the mixture of the water and air which passes in a second through KL is $= 6{,}1\,a^2\sqrt{(a+b-1{,}4)}$. We must deduct from the quantity $(a+b-1{,}4)$ that height which answers to the velocity the water must lose by that portion of velocity which it communicates to the air laterally introduced; but this quantity is so small that it may be neglected in the calculation. The water which passes in the same time of one second thro' BC is $= 0{,}4\,a^2\sqrt{(a+0{,}1)}$. Consequently, the quantity of air which passes in one second through KL, will be $= 6{,}1\,a^2\sqrt{(a+b-1{,}4)} - 0{,}4\,a^2\sqrt{(a+0{,}1)}$, taking the air itself, even in its ordinary state of compression, under the weight of the atmosphere. It will be proper, in practical applications, to deduct one fourth from this quantity; 1. On account of the shocks which the scattered water sustains against the inferior part of the tube, which deprive it of part of its motion; and, 2. Because it must happen that the air in LK will not, in all its parts, have acquired the same velocity as the water.

If the pipe O do not discharge the whole quantity of air afforded by the fall, the water will descend at XZ; the point K will rise in the pipe, the afflux of air will diminish, and part of the wind will issue out of the lower lateral apertures of the pipe BK.

We shall not here examine the greater or less degree of perfection of the different forms of water blowing machines which are used at various iron forges; such as those of the Catalans, and elsewhere. These points may be easily determined from the principles here laid down, compared with those established in the articles *Resistance of Fluids (Encycl.)*, and Dynamics (*Supplement.*).

WEAVING (see *Encycl.*) is an operation, which, by means of a well-known instrument called the *weaving-loom*, has hitherto been performed by bodily labour. That labour is pretty severe; and Mr Robert Millar, an ingenious calico-printer in the county of Dumbarton, Scotland, wishing to lessen it, invented, some years ago, a weaving-loom, which may be wrought by water, steam, horses, or any other power. For his invention he received a patent, dated June 26th 1796; and though truth compels us to say, that we do not think it likely to emulate the spinning machine of Arkwright, it is sufficiently ingenious to deserve notice in a Work of this kind. The following is his own description of his patent weaving-loom:

Fig. 1. (Plate L.) represents a side view of the loom, AA, BB, CC, DD, being the frame. *a* is an axis (which we shall call the spindle) across the frame. On this axis is a sheeve *b*, two inches thick, having a groove round it, two inches deep, and half an inch wide. The bottom of this groove is circular, except in one part *c*, where it is filled up to the top; a lever *d* rests on the bottom of this groove, and is lifted up by it when the elevation *c* comes round to the situation represented in the figure. By this motion, the lever *d* acts on the ratchet-wheel *e* by the catch *t*, and draws it forward one tooth, each revolution of the sheeve. This ratchet wheel is in an iron frame *g g*, which also properly carries the two catches *t* and *u*, which are connected with it at *v*. The catch *u* holds the ratchet-wheel in its position, while the lever *d*, and the catch *t*, are moved by the groove *c* in the sheeve. On the arbor

 of

Weaving of the ratchet is a small pinion *h*, working in the wheel *f*; this wheel is fixed on the end of the roller *e* of fig. 3. On the side of the sheeve *b* is fixed a wiper *k*, which lifts the treadle *l*. This treadle turns on its joints in the sheeve E, which is fixed to the side of the frame A and D; it is kept pressing on the bottom of the groove in the sheeve by a spring *m*, fixed to the frame side A, and having a slender rod *n* from its extremity, joining it with the treadle at *l*. From the point of the treadle there goes a belt *o*, which passes over the pulley *p*, which is seen edgewise in this figure, and is joined to the top of the fly pin *q*, of fig. 2. At the end of the frame A is the short post F; on this rests the yarn-beam *j*, having a sheeve *r*, over which passes a cord, having a weight *s* suspended to it. The other end of this cord is fastened to the spring *v*; the weight causes the yarn-beam to stretch the web from the ratchet wheel *e*, with its catch *u*; and the spring *v* allows the rope to slide on the sheeve as the ratchet is drawn round during the working.

Fig. 2. is a front view of the loom. *a a* is the spindle which carries the sheeve *b*, and the wipers *d* and *d*, which move the treadles *w*, *w*, of fig. 1. These use the treadles of the headles, with which they are connected by cords from the shafts of the headles *s*, *s*. From the upper shaft there go two leathern belts *f*, *f*, to the roller *y*, furnished each with a buckle, for tightening them at pleasure. The two wipers *c*, *c*, on the shaft *a*, which serve for taking back the lay, have the two treadles *x*, *x*, in fig. 3. with a belt from each passing over the roller *h* 2 of fig. 1. and fixed to the sword of the lay. From the swords of the lay forward is fixed a belt to each end of the roller *i*; from this roller there goes a cord to the spring *j*, which serves for taking forward the lay which is hinged on the rocking tree *t*. The star-wheel *b* of fig. 3. and the sheeve *b* of fig. 1. are fixed to the opposite ends of the spindle *a* without the frame; and both the wheel and sheeve have a wiper *k* fixed to them for moving the treadles. In order to drive the shuttle, the belts *o*, *o*, go from the points of the treadles, over the pulleys *p*, *p*, to the top of the fly-pin *q*: This turns on a pin joint in a rail *r*, which goes across the loom. From its lower end there go two small cords to the shuttle drivers *g*, *g*, which slide on the iron rods *n*, *n*. A long iron rod *v* goes across the lay, and is hung on two centres at the ends. In this rod *v* are fixed two small crooked wires *w*, *w*, which are more distinctly marked in the little figure *w* above, which represents a section of the lay. The dot at the lower end of the wire *w*, in this figure, is the section of the rod *v*. The shuttle passes between these wires and the lay every shot, and lifts them up, causing the rod *v* to turn round a little. But if the shuttle should not pass these wires, nor lift them, it would be drawn home by the lay, and destroy the web. To prevent this, there is fixed on one end of the rod *v* a stout crooked wire *z*, having a broad or flat head, which naturally rests on a plate of iron, marked and fixed to the back of the lay. This plate has a slit in its middle about an inch deep. In this slit rests the rod *a* 2 of fig. 3. on which is a short stud which is caught by the wire *z* when the wire *w* is not lifted back by the passing shuttle. This will stop the lay from coming home, and will set off the loom.

Fig. 3. is another side-view of the loom opposite to fig. 1. On the spindle *a* is the star wheel *b*, on the outside of the loom-frame, on the arms of which wheel is fixed the wiper *k*, as the similar wiper is fixed to the sheeves on the other end of the spindle. The wipers which drive the shuttles are fixed on opposite squares of the spindle, and work alternately. Below the star-wheel is a pinion *c*, which is on a round spindle, turned by the water-wheel, by means of a wheel on this spindle. In a wheel on this spindle are two studs, on which the pinion *c* slides off and on as the loom is set off and on by the lever *d*. At the farther end of this lever is the weight *s*, hanging by a cord which passes over a pulley *t*, fixed at the outer end of the spring-catch on which the lever *d* rests; and thus the loom is drawn in at the upper end of the lever *d*. But when the shuttle does not lift the wire *z*, it catches on the stud on the rod *a* 2, which is connected with the spring-catch, and the lever *d* flies off with the weight *s*, and the loom stops working. On the head of the post F is the yarn-beam. The rollers *e* and *f* are cylinders, pressed together by a screw-lever, and take away the cloth between them at a proper rate. In the roller *f* is a groove for a band for driving the roller *g*, on which the cloth winds itself as it is wrought. Wherever springs are mentioned to be used in the above description, weights may be used in their stead, and to the same effect, and more especially upon the treadle of fig. 1. for driving the shuttle.

WEIGHTS AND MEASURES, in commerce, are so various, not only in different countries, but even in different provinces of the same country, and this variation is the source of so much inconveniency in trade, that writers on political and commercial economy have proposed various methods for fixing an universal and immoveable standard of weights and measures for all ages and nations. Sir James Stewart Denham's speculations on this subject have been noticed in his life published in this *Supplement*; Mr Whitehurst's ingenious contrivance for establishing a standard of weights and measures has been mentioned under the title MEASURE (*Encycl.*); and the new table of weights and measures, which the French republicans wish to impose upon all Europe, is given (*Encycl.*) under the title REVOLUTION, n° 183.

As these measures occur frequently, even in English translations of French books of value, we shall here give such an account of them as may enable the reader to reduce them with ease to the English standards. They are of five kinds; *measures of length*, *of capacity*, *of weight*, *of superficies for land*, *and of wood for fuel*. For every kind, there are many measures of different sizes, one of which has been taken as the basis of all the rest, and its name assumed as the root of their names. Thus METRE is called the principal measure of length; LITRE, of capacity; GRAMME, of weight; ARE, of superficies of land; and STERE, of wood for fuel. These words being the radical terms of the names of other measures of length, capacity, &c. a relation is hereby preserved between the names.

The measures of length above the *metre*, are ten times, a hundred times, a thousand times, ten thousand times, greater than the metre. The measures of length below the metre, are ten times, a hundred times, a thousand times, less. To form the names of these measures, other words which indicate the relations of *ten times*, *a hundred*

Weights. *hundred times*, greater; and of *ten times*, a *hundred times*, less. &c. are placed before the word *metre*. The same annexes have been used to form the names of measures, greater or less, than the *litre*, the *gramme*, &c. It is necessary, therefore, to state in this place the English equivalents of only the *metre*, the *litre*, the *gramme*, the *are*, and the *stere*.

The METRE = 3.28084 feet English.

The LITRE = 61.0243 cubic inches, or $1\frac{101}{131}$ pint ale measure.

The GRAMME, or cubic *centi-metre* of water, at the freezing point, = $\frac{1}{454}$ lb. averd. or $\frac{1}{28}$ of an ounce, or $\frac{9}{16}$ of a dram nearly.

The ARE = $1076\frac{1}{7}$ square feet, or $119\frac{1}{2}$ square yards, or $\frac{1}{40}$ of an acre nearly.

The STERE, or cubic metre = 35.31467 cubic feet.

The better part of our countrymen, not choosing to adopt the weights and measures prescribed to them by the French Convention and the National Institute, Sir George Shuckburgh Evelyn, Bart. turned his attention to this subject, and published, in the Philosophical Transactions for 1798, an account of some endeavours to ascertain a standard of weights and measures. The principles upon which he proceeded are the same with Mr Whitehurst's; but he has carried his experiments much further than his predecessor, and seems to have conducted them with greater accuracy. His memoir is hardly susceptible of abridgment; and our limits do not permit us to insert it entire. This is indeed unnecessary, if it be true, as another ingenious gentleman alleges *, that we are in the actual possession, and the constant use, of a standard both for weight and measure, as invariable as that now used in France. This standard he finds in the foot measure, and in the avoirdupoise, or, as he thinks it ought to be called, the *decade* ounce weight.

* H. Goodwin, Esq; in *Nicholson's Journal*, vol iv. p. 163, &c.

The decade ounce weight of pure rain, or distilled water, at 60° of heat, is generally allowed to be equal in bulk to the one-thousandth part of the cubic foot. Were 44.3511 parts out of 10000, or about $\frac{1}{225}$th part added to the present Winchester bushel, that bushel would then contain exactly 10 cubic feet or 10000 oz. of distilled water, at 60° of heat.

Our author then gives comparative tables between this system and that which is now established in France. Taking the metre at 3 French feet, and 11.296 lines †, and the French foot to be to the English as 1 : 1.065752004 ‡, one French foot will be equal to 10.65752004 English decades, or tenths of an English foot: hence he calculates the following

† *Journal de Phys.* vol v. p. 460.

‡ *Phil. Trans.* 1768, p. 326. and *Connoissance des Temps*, 1795.

COMPARATIVE TABLES, English with French.

LONG MEASURE.

Long decade.	Metre.		Metre.	Long decades.
1	= 0.03047983	fere	1 =	32.808583358, &c. or inches 39.3703.

SQUARE MEASURE.

Square decades.	Ares.		Ares.	Square decades.
1	= 0.0000092902	fere	1 =	107640.3142, or sqr. inch. 155002.052448

CUBE MEASURE.

Cube decades.	Litres.		Litre.	Cube decades.
1	= 0.02831637	fere	1 =	35.3152622, &c. or cub. inch. 61.0247727

WEIGHTS.

Avoird or decade oz.	Grammes.		Gramme.	Decade oz.
1	= 28.31637	fere	1 =	0.03531526, &c. or grains, 15.45042625

Long, Square, or Cube, decades are reduced to Long, Square, or Cube, English inches by multiplying by 1.2, 1.44, 1.728; and decade ounces are reduced to grains, containing 7000, or 5760, to the lb. Avoird. or Troy, by multiplying the ounce by 437.5 = the number of grains in an avoirdupoise ounce.

Our author, who seems to have paid much attention to weights and measures, observes, that a standard measure for the purposes of trade, in particular, as well as for others, that would uniformly give an accurate result, and could be easily made, examined, and ascertained, by common mechanics, which neither our present liquid nor dry measures evidently can, would surely be an acquisition of great value. Such an one, he presumes, would be the following: A square pyramid, whose perpendicular height is exactly thrice the length of the side of the base: for such an one, and every section of it, made by a plane parallel to its base, would, in the first instance, possess, and, in every subdivision, retain these remarkable properties.

1st, Similar comparative dimensions to those above given, for the original pyramid, *i. e.* every smaller pyramid, formed by the above mentioned parallel section, would have its perpendicular height thrice the length of the side of its base; and,

2dly, The length of the side of each base will always indicate, or equal the cube root of the solid content of the pyramid; *e. g.* If the length of the side of the base be 3, the solid content will be the cube of 3, *viz.* $3 \times 3 \times 3 = 27$.

We do not perceive very clearly the great value of this standard; but Mr Goodwyn says, that he has been many years in the habit of using a pyramid measure to examine corn; and is perfectly convinced that such a one will indicate a far more accurate result than can arise from the manner in which corn is measured by the bushel. This we are bound to believe; for it is absurd to oppose theories to a fact ascertained by experience.

Westringia. WESTRINGIA, a new genus of plants described by J. E. Smith, M. D. president of the Linnæan Society of London. It was first discovered in New Holland by Dr Solander, who called it *Cunila Fruticosa*, though it is totally different from the CUNILA (see that article, *Encycl.*), and more resembles rosemary, from which, however, it is likewise different. Its peculiar character is: *Calyx semiquinquefidus, pentagonus; corolla resupinata, limbo quadrifido, lobo longiore erecto, bipartito: Stamina distantia, duo breviora (inferiora) abortiva.* Dr Smith assigns it rather to the *didynamia angiospermia*, placing it immediately after the *Teucrium*, than to the *diandria* class of plants.

Wheat. WHEAT (see TRITICUM, *Encycl.*) has for some years past been at so very high a price, that every hint for increasing its quantity or improving its quality is intitled to notice. In the Leicester Journal for the 6th of December 1799, there is an ingenious paper on the subject of transplanting wheat, as a means of providing against

against the expected scarcity of that necessary of life. It is recommended "to sow, in dry land, at the usual season, as much corn as may be deemed necessary to plant in the spring any number of acres which may be occupied with that article in the following year. When the soil is prepared, a furrow is to be made with a very small plough and one horse, in the centre of the ridge or land, returning back in the same track (this time only of every ridge); then turn towards the left hand, and plough another furrow, about eight or nine inches from the first furrow, turning always to the left hand, till the whole ridge is finished; it will then be formed into trenches, in parallel lines of about eight or nine inches asunder, and imitate what gardeners term drawing of drills. In these furrows the plants are to be laid." Mr John Ainsworth of Clen the experienced author of this communication, says he has practised this method with the most complete success.

It has been likewise practised, on a small scale, with equal success, but we know not in what county. About the end of August 1783, that gentleman threw a small quantity of wheat, which near two years before had been steeped and limed (see WHEAT, *Encycl.*) into an unmanured corner of his garden. In the beginning of February following he had a piece of ground (also unmanured) dug in an open part of his orchard, and he transplanted it on beds of six rows wide, at nine inches asunder every way. It tillered, and spread over the ground so completely, as to prevent even a weed growing among it. It produced admirable corn, and at the rate of near four quarters per acre.

From accurate calculations which he then made, he found that an acre, supposing the seed to be very good, and the plants set at the distance above mentioned, would require only *half a peck* of seed.

Besides the saving of the seed, there are two other material advantages which attend such a method; one is, that some suitable crop may be on the ground all the winter for use; and the other is, that ploughing the ground so late as February, will effectually bury and destroy those weeds which were beginning to vegetate; and before others can spring up, the corn plants have taken to the ground, and so spread over it that the weeds cannot rise, by which means there is a very clean crop, and all the customary expence for weeding is saved.

This author seems to think that wheat will thrive as well, and produce as full a crop, when sown in the spring, as if it had been committed to the ground in the preceding autumn. In the southern counties of England we doubt not but it may; but the case is otherwise in Scotland, where the spring is not so early, and where, from the narrowness of the island, the frost is seldom so severe. We agree, however, with Dr Pike, in thinking it a pity that the way of setting wheat (as done in Norfolk and Suffolk) is not every where more general. The process is indeed tedious and troublesome; and we have often wondered that, among the numberless machines lately contrived to lessen manual labour, none has been invented for dibbling wheat expeditiously and accurately. We are therefore pleased to learn, that Dr Pike himself has turned his attention to the subject, and hopes in the course of this year (1800) to present the public with a *method of setting wheat at* PERFECTLY EXACT *distances through a whole field, and as* EXPEDITIOUSLY *as the common broadcast sowing, which can therefore be applied to farms of any magnitude;* and when a peck of seed is found to be sufficient for an acre (and in some land much less), the saving on a large farm must be immense. We trust to the liberality of his profession, that he will not take out a patent for his invention.

Though we have elsewhere given the usual recipes for preventing smut in wheat, it would be improper to conclude this article without mentioning the very simple one which Mr Wagstaffe of Norwich has uniformly found attended with complete success. This consists in nothing more than immersing the seed in pure water, and repeatedly scouring it therein, just before it is sown or dibbled in the soil. Whether well, spring, or river water be used, is indifferent; but repeated stirring and change of water is essential to remove the particles of infection that may have imperceptibly adhered to the seeds thus purified. The subsequent crop will be perfect in itself, and its seeds, he says, successively so likewise, if there are no adjacent fields from whence this contamination may be wafted. He recommends the same washing, and for the same reason, of barley and oats before they be sown.

WILKIE (William, D. D.), the author of an heroic poem, intitled the *Epigoniad*, was born in the parish of Dalmeny, in the county of West-Lothian, on the 5th of October 1721. He was descended of an ancient family in that county, though his father rented only a small farm, and was poor and unfortunate through life. He was able, however, to give his son a liberal education; and that son, it is said, discovered so early a propensity to the study of poetry, that he began to write verses in his tenth year.

As this wonderful prematurity of genius was never heard of during Wilkie's life, it will probably be considered as a story fabricated to raise the Scottish poet to the same eminence with Pope, whose versification he is allowed to have imitated with success. We have no doubt but that Wilkie wrote in early life the description of a storm, which is published in the 9th volume of the Statistical Account of Scotland; but that he wrote it in his tenth year is not proved, and is highly improbable. The poem displays a notion—a confused notion indeed—of the laws of electricity, which a boy in his tenth year, and at a period when electricity was little understood, could not have acquired.

Having learned the rudiments of the Latin tongue at the parish-school of Dalmeny, young Wilkie was, at the age of thirteen, sent to the university of Edinburgh, where he was soon distinguished by his originality of thought, and by his rapid progress in erudition and science. Among his fellow-students he was most closely associated with Dr Robertson the historian, Mr John Home the poet, Dr M'Ghie (A), who afterwards obtained

(A) According to Sir John Hawkins, this man bore arms on the side of government at the battle of Falkirk 1745. After which, taking a degree in physic, he went to London in hopes of employment through the interest

Wilkie.

tained the friendship of Johnson, and became a member of the Ivy lane Club; and a Mr Cleghorn, who promised be an ornament to the university, in which he was afterwards a professor, but died before he had time to realize the fond hopes of his friends. During the course of his education, Wilkie became acquainted with the celebrated David Hume and Dr Ferguson, and at a later period with Dr Adam Smith, the far-famed author of "The Wealth of Nations." Of all those men he regarded Dr Ferguson with the greatest affection, and Dr Smith with the greatest admiration. This last writer he considered as equal to Robertson and Hume in erudition, and vastly their superior in originality and invention; and this opinion he cherished to the day of his death.

Before he had completed his education, his father died, leaving him no other inheritance than the stock and unexpired lease of his farm, and the care of his three sisters. Wilkie, therefore, turned much of his attention to agriculture, in which he became eminent, not merely as a theorist, but as a practical farmer. He had too much science to be the slave of ancient prejudice, and too much judgment to be hurried into hazardous experiments by the charms of untried speculation. One of his sisters being married to a skilful, though unlettered farmer, he availed himself of his brother's experience; and upon the facts and maxims derived from him built a system of practical farming, which fully answered his own expectation, and obtained the applause of all his neighbours.

He still prosecuted his studies in the university, and without ceasing to be a farmer became a preacher in the church of Scotland. For some years this made no alteration in the mode of his living. He preached occasionally for the ministers in his neighbourhood; cultivated his farm; read the classics; and, enamoured of the simple sublimity of Homer, projected an epic poem on the Homeric model. The subject of his intended poem he drew from the fourth book of the *Iliad*, where Sthenelus gives Agamemnon a short account of the sacking of Thebes; and as that city was taken by the sons of those who had fallen before it, Wilkie gave to his poem the quaint title of *Epigoniad*, from the Greek word ἐπίγονοι, which signifies *descendants*. It is not our business to write a criticism upon this poem. The subject was ill-chosen; for the learned reader has enough of the heroic ages in the immortal poems of Homer and Virgil, and in those ages the unlearned reader can feel no interest. The Epigoniad, therefore, though composed in smooth and elegant verse, with due attention to ancient manners, and constructed on the most regular plan, has fallen into neglect, from which no critic or biographer will ever rescue it.

In the year 1753, Mr. Wilkie was ordained minister of Ratho, in consequence of a presentation from the Earl of Lauderdale, who knew his worth and admired his genius. Without neglecting his favourite amusements of husbandry, or the study of the belles lettres, he discharged with fidelity the duties of a Christian pastor, was famed for his original and impressive mode of preaching, and soon came to be loved as well as esteemed by his rural flock.

In the year 1757 the Epigoniad was published, the result of fourteen years study and application, which might surely have been more usefully employed on some other work; and in 1759 a second edition was called for, to which he added *A Dream in the manner of Spenser*. He was, the same year, chosen professor of natural philosophy in the university of St Andrew's; an office for which it is difficult to conceive how he could have been fitted by the study of epic poetry, and close attention to the cultivation of his farm. He was, however, a man of a vigorous mind, and we never heard that he disgraced his electors.

When he removed to St Andrew's, his whole fortune exceeded not L. 200 Sterling; a proof that his Epigoniad had not enriched him. With this sum he purchased a few acres of land in the neighbourhood of the city, carried his two unmarried sisters with him, and continued to live in the university exactly as he had lived at Ratho. In his professorial career there was nothing remarkable. He patronised genius, especially poetical genius, in the young men who attended his lectures, and by them was, of course, loved and esteemed: (See FERGUSSON in this *Suppl.*). In the year 1768 he published a volume of fables of no great value, previous to which the university conferred upon him the degree of D. D.; and he died, after a lingering illness, on the 10th of October 1772.

The manners of Dr Wilkie were singular, and in some respects disgusting. He has been severely blamed for his penuriousness, but, in our opinion, unjustly. His father had left him in debt, with nothing but the profits which he might make of a small farm to discharge that debt, and to support himself and three sisters. In him, therefore, rigid economy was, for many years, a virtue; and he knows little of human nature, who can blame a man for not breaking habits which it had been the duty, as well as the business, of a great part of his life to form. Amidst his most rigid and offensive economy, he was liberal in his donations to the poor.

He had been seized, while minister of Ratho, with an unformed ague, of which he never got entirely rid. For this complaint he thought an extraordinary perspiration necessary, and generally slept, in winter, under twenty-four blankets. He had an utter aversion from clean linen, and has been known to bargain, when he staid a night from home, not only for the proper quantity of blankets to his bed, but also for sheets, which had been used by some other person, and rendered sufficiently dirty to please his feeling. It will easily be conceived that such a man was, to the last degree, slovenly in his dress.

Suspicions have been thrown out by his latest, and we believe his only, biographer, that Dr Wilkie's belief of the Christian religion was neither orthodox nor steady. Not having had the pleasure of his acquaintance, we cannot positively say that these suspicions are groundless; but the writer of this article has conversed much about the author of the Epigoniad with a clergy-

rest of his countrymen, and perhaps in return for his loyalty. He was a learned, ingenious, and modest man; but so little successful in his profession, that he died of a broken heart, and was buried by a contribution of his friends.

man who knew him well, and who would have been glad to accuse him of infidelity, if he could have preferred such an accusation with truth. He was a very absent man, apt to forget what he was about even when discharging the most solemn parts of his clerical duty, and used to say of himself that he never could conduct a sacrament. From this absence of mind, and those confessions of it, may have arisen the suspicion that he was not a firm believer; but no such suspicion was ever thrown out to this writer by the clergyman already referred to.

He had one very extraordinary defect in a poet: He could not read aloud the smoothest verses, so as to preserve either the measure or the sense of them. Of this Dr Anderson has produced very complete proof in his life of Wilkie, prefixed to his poetical works in the Edinburgh edition of the British Poets. With all his defects, however, and all his foibles, he was unquestionably a genius, and, we are inclined to believe, a good man.

WINES (see that article, *Encycl.* and *Vegetable Substances, Suppl.*) are so often adulterated with minerals prejudicial to the health, that various methods have been devised for detecting the adulteration. The property which liver of sulphur (alkaline sulphures) and hepatic air (sulphurated hydrogen) possess of precipitating lead in a black form, has been long ago made public; and this property has been employed to determine the quality of wines by means of the *liquor probatorius Wirtembergensis*, or Wirtemberg proving liquor. But in trying wines supposed to have been adulterated, this proof does more hurt than service, because it precipitates iron of the same colour as the pernicious lead. Many wine-merchants, therefore, of the greatest respectability, rendered by these means suspected, have been ruined.

The following is recommended by M. Hanhemann as a better test of sound wines than the proving liquor of Wirtemberg. Mix equal parts of oyster shells and crude sulphur in a fine powder, and put the mixture into a crucible. Heat it in a wind furnace, and increase the fire suddenly, so as to bring the crucible to a white heat, for the space of 15 minutes. Pulverise the mass when it is cool, and preserve it in a bottle closely stopped.

To prepare the liquor, put 120 grains of this powder, and 120 grains of cream of tartar (acidulous tartarite of potash), into a strong bottle; fill the bottle with common water, which boil for an hour, and then let it cool; close the bottle immediately, and shake it for some time: after it has remained at rest to settle, decant the pure liquor, and pour it into small phials capable of holding about an ounce each, first putting into each of them 20 drops of muriatic acid. They must be stopped very closely with a piece of wax, in which there is a small mixture of turpentine.

One part of this liquor, mixed with three parts of suspected wine, will discover, by a very sensible black precipitate, the least traces of lead, copper, &c. but will produce no effect upon iron, if it contains any of that metal. When the precipitate has fallen down, it may still be discovered whether the wine contains iron, by saturating the decanted liquor with a little salt of tartar (tartareous acidulum of potash), by which the liquor will immediately become black. Pure wines remain clear and bright after this liquor has been added to them.

WOOD-CUTS are engravings on wood, commonly on box, which, in many cases, are used with advantage instead of copper-plates. The art of cutting or engraving on wood is undoubtedly of high antiquity; for Chinese printing is a specimen of it. (See CHINA, n° 127 *Encycl.*) Even in Europe, if credit be due to Papillon, this art was practised at a period considerably remote; for he mentions eight engravings on wood, entitled, "A representation of the warlike actions of the great and magnanimous Macedonian king, the bold and valiant Alexander; dedicated, presented, and humbly offered, to the most holy father, Pope Honorius IV. by us Alexander Alberic Cunio Chevalier, and Isabella Cunio, &c." This anecdote, if true, carries the art of cutting in wood back to 1284 or 1285; for Honorius occupied the papal throne only during these two years. Even this is not the remotest period to which some have carried the art in Europe; for the use of seals or signets being of very high antiquity, they imagine that the invention of wood-cuts must be coeval with them. The supposition is certainly plausible, but it is not supported by proof. The earliest impression of a wooden-cut, of which we have any certain account, is that of St Christopher carrying an infant Jesus through the sea, in which a hermit is seen holding up a lantern to shew him the way; and a peasant, with a sack on his back, climbing a hill, is exhibited in the back ground. The date of this impression is 1423.

In the year 1430 was printed at Haarlem, "The history of St John the evangelist and his revelation, represented in 48 figures in wood, by Lowrent Janson Coster;" and, in 1448, Jorg Schappf of Augsburg cut in wood the history of the Apocalypse, and what was called *The poor man's bible*. (See ENGRAVING, *Encycl.* page 668.)

A folio chronicle, published 1493 by Schedal, was adorned with a vast number of wood-cuts by William Plydenwurff and Michael Wolgemut, whose engravings were greatly superior to any thing of the kind which had appeared before them. Wolgemut was the preceptor of Albert Durer, whose admirable performances in this department of art are justly held in the highest esteem even at the present day.

About this period it became the practice of almost all the German engravers on copper to engrave likewise on wood; and many of their wood cuts surpass in beauty the impressions of their copper-plates. Such are the wood-cuts of Albert Aldtorfer, Hisbel Pen, Virgil Soles, Lucas van Cranach, and Lucas van Lyden, the friend and imitator of Albert Durer, with several others.

It appears that the Germans carried this art to a great degree of perfection. Hans or John Holbien, who flourished in 1500, engraved the *Dance of Death*, in a series of wooden-cuts, which, for the freedom and delicacy of execution, has hardly been equalled, and never surpassed.

Italy, France, and Holland, have produced many capital artists of this kind. Joan. Tornæsium printed a bible at Lyden, in 1554 (a copy of which we have seen), with wooden-cuts of excellent workmanship. Christopher Jegher of Antwerp, from his eminence in the art, was employed by Rubens to work under his inspection,

Wood-cuts. inspection, and he executed several pieces which are held in much estimation; the character of these is boldness and spirit.

The next attempt at improvement in this art was by Hugo da Carpi, to whom is attributed the invention of the *chiaro scuro*. Carpi was an Italian, and of the 16th century; but the Germans claim the invention also, and produce in evidence several engravings by Mair, a disciple of Martin Schoen, of date 1499. His mode of performing this was very simple. He first engraved the subject upon copper, and finished it as much as the artists of his time usually did. He then prepared a block of wood, upon which he cut out the extreme lights, and then impressed it upon the print; by which means a faint tint was added to all the rest of the piece, excepting only in those parts where the lights were meant to predominate, which appear on the specimens extant to be whitened with white paint. The drawings for this species of engraving were made on tinted paper with a pen, and the lights were drawn upon the paper with white paint.

There is, however, a material difference between the *chiaro scuros* of the old German masters and those of the Italians. Mair and Cranach engraved the outlines and deep shadows upon copper. The impression taken in this state was tinted over by means of a single block of wood, with those parts hollowed out which were designed to be left white upon the print. On the contrary, the mode of engraving by Hugo da Carpi was, to cut the outline on one block of wood, the dark shadows upon a second, and the light shadows, or half tint, upon a third. The first being impressed upon the paper, the outlines only appeared: this block being taken away, the second was put in its place, and being also impressed on the paper, the dark shadows were added to the outlines; and the third block being put in the same place upon the removal of the second, and also impressed upon the paper, made the dim tints, when the print was compleated. In some instances, the number of blocks were increased, but the operation was still the same, the print receiving an impression from every block.

In 1698, John Baptist Michel Papillon practised engraving on wood with much success, particularly in ornamental foliage and flowers, shells, &c. In the opinion, however, of some of the most eminent artists, his performances are stiff and cramped. From that period the art of engraving on wood gradually degenerated, and may be said to have been wholly lost, when it was lately re-invented by Mr Bewick of Newcastle.

This eminent artist was apprentice to Mr Bielby, an engraver on metal of the very lowest order, who was seldom employed in any thing more difficult than the cutting of the face of a clock. Application having been made to this man for a wood-cut or two of the most trifling description, the job was given to Thomas Bewick; by whom it was executed in such a manner, that Mr Bielby, who was accustomed to employ his apprentices in such work, advised him to prosecute engraving in that line. The advice was followed; and young Bewick inventing tools, even making them with his own hands, and sawing the wood on which he was to work into the requisite thickness, proceeded to improve upon his own discoveries, without assistance or instruction of any kind. When his apprenticeship expired, he went to London, where the obscure wood-engravers of the time wished to avail themselves of his abilities, while they were determined to give him no insight into their art. He remained some years in London; and during that time, if we mistake not, received from the *Society for the Encouragement of Arts, &c.* a premium of considerable value for the best engraving in wood. Returning to Newcastle, he entered into copartnership with his old master; and established his reputation as an artist by the publication of his admirable History of Quadrupeds. This was followed by his History of Birds, of which only one volume has yet (1800) appeared.

John Bewick, brother to Thomas, learned the art of him, and practised it for several years in London with great applause. His abilities, however, though respectable, were not, by the best judges, deemed so brilliant as his brother's; and owing to bad health, and the nature of his connection with the booksellers and others, he seems not to have advanced the art beyond the stage at which he received it. He died, three or four years ago, at Newcastle.

Mr Nesbit, who executed the admirable Hudibras published by Vernor and Hood (A), and Mr Anderson, whose beautiful cuts adorn the poem entitled *Grove Hill*, were the next, and hitherto have been the last of Thomas Bewick's pupils, who have appeared before the public as artists. By these gentlemen we are authorized to say, that the method practised by the ancient engravers on wood, whose works are still admired, must have been different from that of Bewick and his pupils. What that method was seems to be altogether unknown. Papillon, who writes the best history extant of the art, guesses indeed in what manner the old engravers proceeded so as to give to their works the spirit and freedom for which they are famed; but that his guesses are erroneous seems evident from the stiffness of his own works. The principal characteristic in the mechanical department of the productions of the ancient masters is the crossing of the black lines, which Papillon has attempted with the greatest awkwardness, though it seems to have been accomplished by them with so much ease, that they introduced it at random, even where it could add nothing to the beauty of the piece. In Bewick's method of working, this cross hatching is so difficult and unnatural, that it may be considered as impracticable (B).

The engravers of Bewick's school work on the end of the wood which is cut across the trunk of the tree, in

(A) The designs were by Thornton; and the cuts from them have been compared to Holbein's far-famed Dance of Death.

(B) Mr Nesbit has indeed introduced something of it into two or three of his pieces, merely to shew that he *could* do it; but so great was the labour, and so little the advantage of this improvement, if such it can be called, that probably it will not be attempted again.

Wood-cuts. is pieces of the proper thicknefs. As wood-cuts are generally employed in the printer's prefs amidft a form of types, this thicknefs muft be regulated by the height of the types with which they are to be ufed. The tools employed are nearly the fame with thofe ufed in copperplate engraving, being only a little more deep, or lozenge, as engravers call it. They muft have points of various degrees of finenefs for the different purpofes to which they are applied, fome of them being fo much rounded off at the bottom as to approach to the nature of a goodge, whilft others are in fact little chiffels of various fizes. Thefe chiffels and goodges, to which every artift gives the fhape which he deems moft convenient, are held in the hand in a manner fomewhat different from the tool of the engraver on copper, it being neceffary to have the power of lifting the chips upwards with eafe. To attempt a defcription of this in writing would be in vain; but it is eafily acquired, we are told, by practice.

The pupils of the fchool of Bewick confider it as quite improper to fpeak of his invention as a revival of the ancient art. Some old prints, it is true, have the appearance of being executed in the fame way with his; but others have certainly been done by a method very different. It is therefore not fair to appreciate the prefent art by what has been done, but by what may be done; and that remains yet to be fhewn. The art is in its infancy; and thofe who are difpofed to compare it with the art of engraving on copper, ought to look back to the period when copperplate engraving was of as recent invention as Bewick's method of engraving on wood. Marc Antonio, who engraved under the direction of the great painter Raphael, thought it no mean proof of his proficiency in his art, that he was able to imitate on copper plates the wood-cuts of Albert Durer; and Papillon is highly indignant that there fhould have been perfons fo very blind as to miftake the copies for the originals. If copper has its advantages over wood in point of delicacy and minutenefs, wood has, in its turn, advantages not inferior in regard to ftrength and richnefs. Thofe prints which were executed under the aufpices of Titian and Rubens, will always remain a monument of the fpirit and vigour natural to wood engraving; and if there be not found in them all the attention to *chiaro fcuro*, which the prefent age demands, it muft not be attributed either to defect in the art, or to want of abilities in the artifts, but to the tafte of the times when *chiaro fcuro* was little underftood. It remains for fome enterprifing artift to fhew that the vigour of the ancient art may be attained by the prefent one, and at the fame time to add to that vigour thofe gradations of fhade which are fo much admired in good copperplates. As there feems to be a more perfect, or at leaft a more pleafant black produced by wood than by copperplate printing, and certainly a more perfect white (c), who will fay that any intermediate fhade whatever may not be produced by wood-cuts? To attempt this on a fmall fcale would indeed be vain, becaufe the flighteft variation, produced by a little more or lefs ink, or a harder preffure in printing, bears fuch a proportion to a very fhort line, as muft neceffarily render the attempt abortive.

Wood-engraving, therefore, muft always appear to disadvantage while it is confined to fmall fubjects, and will never reach its ftation *as a fine art*, till thofe who are engaged in its cultivation improve upon the difcoveries of one another, and apply to fubjects to which it is properly adapted. As an *economical art* for illuftrating mechanics and other fubjects of fcience, it is too little employed even in its prefent ftate. Wood-cuts, Wool-combing.

The works of Bewick and his pupils, which have hitherto been publifhed, are not numerous. Befides his quadrupeds and birds, the Hudibras by Nefbit, and the Grove Hill by Anderfon, which have been already noticed, we are acquainted with none but the following:—Goldfmith's *Traveller* and *Deferted Village* with elegant plates, all by Thomas Bewick, except one or two which were executed by John; Somerville's *Chace* by the fame artifts, executed in a ftyle of elegance which perhaps has never been furpaffed; a View of St Nicholas's Church, Newcaftle, 15 inches long, by Mr Nefbit, who received for it a filver medal from the Society for the Encouragement of Arts, and an honorary letter from the Society of Antiquaries.

WOOL-COMBING, a well known operation, which, when performed by the hand, is laborious, tedious, and expenfive. The expence of it through all England has been calculated at no lefs a fum than L. 800,000; and to leffen this expence, the Rev. Edmund Cartwright of Doncafter in Yorkfhire bethought himfelf, fome years ago, of carding wool by machinery. After repeated attempts and improvements, for which he took out three patents, he found that wool can be combed in perfection by machinery, of which he gives the following defcription:

Fig. 1. Is the crank lafher. A is a tube through which the material, being formed into a fliver, and flightly twifted, is drawn forward by the delivering rollers. B, a wheel faft upon the crofs-bar of the crank C, a wheel, on the oppofite end of whofe axis is a pinion working in a wheel upon the axis of one of the delivering rollers. Plate L.

Note, When two or more flivers are required, the cans or bafkets, in which they are contained, are placed upon a table under the lafher (as reprefented at D), which, by having a flow motion, twifts them together as they go up.

Fig. 2. Is the circular clearing comb, for giving work in the head, carried in a frame by two cranks. Fig. 3. The comb-table, having the teeth pointing towards the centre, moved by cogs upon the rim, and carried round upon trucks, like the head of a windmill. *a*, *b*, the drawing rollers. *c*, *d*, callender, or conducting rollers.

Note, Underneath the table is another pair of rollers, for drawing out the backings.

In the above fpecification, we have omitted the frame in which the machine ftands, the wheels, fhafts, &c. Had thefe been introduced, the drawing would have been crowded and confufed; befides, as matters of information, they would have been unneceffary, every mechanic, when he knows the principles of a machine, being competent to apply the movements to it.

The wool, if for particular nice work, goes through three operations, otherwife two are fufficient: the firft operation

(c) The parts of the print intended to be white are not even touched by the wood-block.

Wool-combing. operation opens the wool, and makes it connect together into a rough fliver, but does not clear it. The clearing is performed by the second, and, if neceffary, a third operation. A fet of machinery, confifting of three machines, will require the attendance of an overlooker and ten children, and will comb a pack, or 240lb. in twelve hours. As neither fire nor oil is neceffary for machine-combing, the faving of thofe articles, even the fire alone, will, in general, pay the wages of the overlooker and children; fo that the actual faving to the manufacturer is the *whole* of what the combing cofts, by the old imperfect mode of hand-combing. Machine-combed wool is better, efpecially for machine-fpinning, by at leaft 12 *per cent.* being all equally mixed, and the flivers uniform, and of any required length.

Z.

Zaminy, Zemindars. ZAMINY, in the language of Bengal, fecurity.

ZEMINDARS, the great landholders of Bengal. This is the original fenfe of the word; but it is now more ftrictly applicable to thofe who have their title conftituted or confirmed by a patent or charter from government, by which they hold their lands or Zemindaries upon certain conditions. As far as can be afcertained from the narrations of hiftory, it appears that, in times prior to the irruptions of the Mahomedans, the rajahs who held their refidence at Delhy, and poffeffed the fovereignty of Hindoftan, deputed officers to collect their revenues (Kherâje), who were called in the Indian language *Choudheries*. The word *Zemindar* is Perfian, and that language can have had no currency in the countries of India, until it was introduced by the people of Perfia. When the Emperor Shehâb ul-Dien Ghory conquered the empire of Hindoftan (A), he left Sultan Cutub ul Dien to be his viceroy at Delhy, and adminifter the government of Hindoftan. From that time the cuftoms and practices of the Mahomedans began gradually to be eftablifhed in India; their armies were fent into the countries of the reduced Rajahs, under the command of Omrahs, in order to preferve the conqueft; and lands were allotted to them to defray the expence. From hence arofe the fyftem of Jaghiredarry in Hindoftan. But when thefe Omrah Jaghiredars had eftablifhed their own ftrength, feveral of them rebelled againft the imperial authority, and afpired at the crown. Thus circumftanced, the emperors, in order to obviate thefe mifchiefs, thought it would be more politic to commit the management of the country to the native Hindoos, who had moft diftinguifhed themfelves by the readinefs and conftancy of their obedience to the fovereign power.

In purfuance of this plan, diftricts were allotted to numbers of them under a reafonable revenue (Jummah Monâfib), which they were required to pay in money to the governors of the provinces, deputed from the Emperor. And in cafe any one of the Omrahs or provincial governors fhould fwerve from his allegiance, the Zemindars of that country were to exert themfelves in fuch a manner as fhould check rebellion, and reftore good government. For this purpofe, grants of Zemindary were feverally conferred upon fuch of the Hindoos as were obedient; defcribing their apportionment of the country; and every perfon who had received a grant under the authority of the crown was thereby fully invefted with the functions of Zemindar.

Zemindars. The functions of a Zemindar are, 1ft, The prefervation and defence of their refpective boundaries from traitors and infurgents; 2dly, The tranquillity of the fubjects, the abundance of cultivators, and increafe of his revenue. 3dly, The punifhment of thieves and robbers, the prevention of crimes, and the deftruction of highwaymen. The accomplifhment of thefe objects is confidered in the royal grant as the difcharge of office to the fovereign; and on that account the word *office* (Khidmut) is employed in the Dewanny Sunnud for a Zemindary.

It was a rule in the times of the ancient emperors, that when any of the Zemindars died, their effects and property were fequeftrated by the government. After which, in confideration of the rights of long fervice, which is incumbent on fovereigns, and elevates the dignity of the employer, Sunnuds for the office of Zemindary were granted to the children of the deceafed Zemindar; and no other perfon was accepted, becaufe the inhabitants could never feel for any ftranger the attachment and affection which they naturally entertain for the family of their Zemindar, and would have been afflicted if any other had been put over them. For this reafon, the emperors, confidering it as a means of conciliating the minds of the people, gracioufly fixed and confirmed the children of the deceafed Zemindar in the office of their fathers and grandfathers, by iffuing new funnuds to transfer the poffeffion to them. By degrees Zemindaries became truly heritable property, which, however, could be transferred by gift or fale from one family to another. They could likewife be forfeited to the fovereign, by the Zemindar's deviating from his allegiance, neglecting to pay his tribute, or to difcharge the duties of his ftation.

It is univerfally known, fays Sir Charles Roufe Boughton, that, when the three provinces of Bengal, Bahar, and Oriffa, were ceded to the Britifh Eaft India Company, the country was diftributed among the Zemindars and TALOOKDARS (fee that article in this Vol.), who paid a ftipulated revenue, by twelve inftalments, to the fovereign power or its delegates. They affembled at the capital in the beginning of every Bengal year (commencing in April), in order to complete their final payments, and make up their annual accounts; to fettle

(A) This event took place towards the clofe of the 12th century. N. B. *Kherâje* fignifies fpecifically the tribute paid by a conquered country.

Zemindars. settle the discount to be charged upon their several remittances in various coins for the purpose of reducing them to one standard, or adjust their concerns with their bankers; to petition for remissions on account of storms, drought, inundation, disturbances, and such like; to make their representations of the state, and occurrences of their districts: after all which they entered upon the collections of the new year; of which, however, they were not permitted to begin receiving the rents from their own farmers, till they had completely closed the accounts of the preceding year, so that they might not encroach upon the new rents, to make up the deficiency of the past. Our author proves, we think completely, the right of the Zemindars to transfer their possessions, either by inheritance to their children, or, with the consent of the sovereign, to other families; and he argues strenuously and successfully against the bad policy, as well as injustice, of interfering with those rights, as long as the Zemindars discharge the duties of their several stations. Zemindars.
